## A

	Page.		Page.
Abbotiakoon Mine .....	296, 300	Alvarado M. & M. Co. ....	129
Absolute title fee, simple or .....	35	Amalgamated Co. ....	506
Accidents at Butte .....	803	Amalgamated Zinc (De Bavay's) Ltd. Company report ..	645
In U. S. Coal Mines .....	780	Amalgamated Copper Co. ....	313, 314, 572
Mine-owners' liability for .....	A. J. Pillsbury... 56	Dividend .....	538
Acetylene gas explosions .....	453	Amalgamated Development Co. ....	61
Acre-foot, used term .....	681	Zinc flotation plant .....	355
Action of oxidizing agents on the velocity of gold in		Amalgamating devices .....	847
potassium cyanide .....	500	Amalgamation at the Homestake .....	
Of minerals, sulphates and arsenates on cyanide solu-		Allan J. Clark and W. J. Sharwood .....	762
tions .....	Andrew F. Crosse... 16	At Bendigo .....	200
Adsorption, definition of .....	714	At Tonopah, no .....	847
Adalbert Mine, in Bohemia .....	233	Amalgamator, Thibault gold .....	848
Afterthought Copper Co. ....	95	American tin production .....	49
Agitating concentrate .....	J. E. Alley... 118	American Association of Commerce & Trade in Berlin,	
Agitation at Oriental Con., Korea .....	653	Editorial .....	38
At Tonopah .....	825	American Construction Co. ....	94
Of slime at Empire mine .....	580	American Cyanamide Co., extensions to plant at Niagara	753
Agitator on the Rand, Hendryx .....	Johannesburg corres-	American Development Mining & Reduction Co. ....	47
pondence .....	599	American Institute of Mining Engineers .....	106, 119, 129
Agitators at Waihi, Brown .....	Douglas Waterman... 375	Ditto .....	1, 73, 102, 262, 360, 487
Step-bearing for slime .....	L. C. Trent... 505	Ditto .....	J. W. Malcolmson... 151
Ditto .....	148	And its affairs .....	406
Agnew, J. A. ....	423, 426	Constitution and by-laws .....	693
Agricola .....	423	Increasing the dues of .....	H. V. Wheeler... 409
Agricola's 'De Re Metallica' .....	Editorial... 423	Meeting of Los Angeles members .....	221
Views on origin of ore deposits .....	427	American Mines Syndicate .....	96
Aguacate Mines .....	129	American Mining Co. ....	129
Ahmeek Copper Co. ....	771	American Mining Congress .....	126
Air blasts in mines .....	516	Ditto .....	Editorial... 295
Compressors at Anaconda .....	724	At Spokane .....	707
Compressors at mines generally .....	723	On mineral land laws .....	685
Compressors, enclosed type, Chicago Pneumatic Tool		Sessions at Spokane .....	Editorial... 615
Co. ....	550	American Potash Co. to build plant .....	808
Air receivers require cleaning out .....	389	Amercan Smelting & Refining Co. ....	94, 104, 126, 185
Replacing steam for hoisting at Anaconda .....	349	Ditto .....	Editorial... 383
Transmission lines, joints in .....	35	Half-yearly report .....	374
Compressor plants at Panama canal .....	160	In the lead market .....	537
Lift at Black Oak Mill .....	689	Omaha, Bag-house at .....	129
Lift practice .....	714	American Tungsten Consolidated Corporation .....	178
Receivers at Anaconda .....	725	American Vanadium Co. ....	94
Used in converter at Great Falls .....	328	American Zinc, Lead & Smelting Co. ....	123
Alaska, Aniak district .....	85	American Zinc Ore Separation Co. plant at Eureka .....	222
Bullion output .....	741	Amounts of platinum, determination of small .....	
Coal .....	Editorial... 649	F. P. Dewey... 87	
Conditions and a program .....	Walter E. Clark... 172	Amblygonite at Peerless mine .....	35
Conditions in .....	Editorial... 164	Amparo Mining Co. ....	635
Copper production .....	601	Mine .....	483
Freight rate reduction .....	129	Output .....	289
Gold mines .....	379	Amphibole in Italy .....	11
Katalla oilfield .....	Arthur Thompson... 169	Anaconda, furnace work at .....	593
Mines .....	89	Increase of wages at .....	184
New dredges in .....	94	Mines and smelter .....	749
Population of .....	415	Output .....	250
Problems .....	U. S. Rush... 181	Anaconda Copper Company .....	313, 314, 319, 349, 353, 443
Problems at Mining Congress .....	718	Hoisting systems .....	554
Trade in 1912 .....	708	Pay-roll at .....	152
Alaska Commercial Co. ....	15	Analysis of salt in Silver Peak marsh .....	827
Alaska Consolidated Copper Co. ....	156	Of Tomboy concentrate .....	820
Alaska Gastineau Co. ....	262, 281	Of water from Nebraska lakes .....	747
Alaska Geological Survey .....	718	Of white metal .....	757
Electric plant .....	510	Analytical work, bottle for .....	830
Alaska Gold Mines .....	277, 313, 314, 348, 350, 605, 674, 836	Work, filtering certain solutions in .....	847
Ditto .....	Editorial... 262, 281, 282	Andesite at National, Nev. ....	655
An Exchange .....	537	Angelo Deep mine .....	266
Alaska Juneau mine .....	Editorial... 135	Aniak district, Alaska .....	85
Alaska Mexican Co. ....	447	Leasing system .....	89
Mine .....	187	Anode tanks, short circuiting in .....	A. R. Ledoux... 52
Output .....	317, 607, 741	Animikite in Ontario .....	226
Alaska mine, Sierra county, California .....	480, 709	Anniversary of contemporaries .....	Editorial... 392
Alaska Perseverance Co. ....	183	Anonymous contributions .....	Editorial... 783
Ditto .....	Editorial... 163	Another Universe .....	307
Mine .....	262, 281	Anthracite coal costs .....	Editorial... 517
Alaska Railway Commission .....	383	Production in Pennsylvania .....	748
Ditto .....	Editorial... 327	Antelope mining district of Nevada .....	170
Alaska Treadwell Co. ....	447	Antimonial tailing .....	191
Ditto .....	Company reports... 227	Tailing, difficulties of cyaniding .....	647
Mine .....	263, 281, 285, 575	Antimony in cyanide treatment .....	728
Mine, power at .....	211	Mining in New South Wales .....	J. E. Carne... 178
Output .....	708, 839	Ore in United States in 1911, no production .....	205
Welfare of employees .....	617	Ore production in United States in 1911 .....	Editorial... 489
Yield for June .....	156	Production .....	160, 226, 489
Alaska United Copper Co. ....	69, 100, 510	Use of .....	614
Alaska United Gold Mining Co. ....	61	Troubles in Rhodesian treatment .....	820
Mine .....	187	Aparoma Goldfields Co. ....	820
Output .....	317, 607	Apex law decision .....	685
Ready Bullion mill of the .....	782	App mine cost .....	522
Alberger Pump & Condenser Co., Hammond meter .....	352	Mine sale .....	Editorial... 750
Aldrich pumps at Aspen .....	362	Appelbaum, Misha E. ... Copper review for September .....	504
Algeria, products of minerals in 1911 .....	569	Ditto .....	Copper review for October... 633
Alkalinity of cyanide solutions in treating certain ores		Ditto .....	Copper review for November... 802
Alleged chemical effects of pressure on mineral meta-		Arabia, mineral discoveries in .....	376
morphism .....	473	Aramayo Francke mines of Bolivia .....	804
Allen, A. H. ... Work on acid production from smelting ores		Arc-lighting station, first .....	714
Alley, J. E. .... Agitating concentrate .....	118	Arcade Mining Co. re-organized .....	842
Alloys, behavior of .....	780	Argentina coal in Neuquen territory .....	53
Insoluble in acid, certain .....	814	Argo Reduction & Ore Purchasing Co. ....	Editorial... 2
Of steel .....	35	Argonaut mine costs .....	522
Altona mine .....	26	Arizona compensation law .....	Editorial... 423
Alumina as a drying agent .....	F. M. G. Johnson... 53	Copper production .....	B. S. Butler... 529
In slags .....	H. C. Bellinger... 114	Dry washings of value—gold placers of .....	
Aluminum as a substitute for tin .....	516	T. Lane Carter... 166	
Consumption of in United States .....	305	Mining law .....	Editorial... 37
Prices fixed .....	365	Tax schedule .....	61

	Page.		Page.		
Taxation of mines.....	Editorial.....	583	Bismuth bearing ore.....	142	
Arizona Copper Co., Ltd.....	318	Black Oak mill.....	Charles H. Urquhart.....	687	
Ditto.....	Company reports.....	679	All sliming.....	687	
Production.....	530	Black sands, examination of.....	Editorial.....	624	
Arizona Empire mine.....	674	Treatment.....	126	625	
Arizona Southwestern M. Co.....	61	Black Bear quartz mine.....	126		
Arkansas Valley plant at Leadville.....	742	Black Eagle antimony mine of Alaska.....	489		
Arroba, meaning of term.....	814	Black Range mine production.....	540		
Value of the Spanish.....	Robert Fraser, Jr.....	633	Blast-furnaces at Mason Valley smelter.....	269	
Arsenates on cyanide solutions, action of mineral sulphates and.....	Andrew F. Crosse.....	16	Furnaces, accumulations.....	442	
Arsenic produced in United States in 1911, white.....	175	Blasting by electricity.....	681		
Use of.....	160, 194	At Panama.....	818		
Arthur Iron Mining Co.....	573	Blowers at Swansea smelting plant.....	799		
Ashio mines and mills improvement at.....	H. Foster Bain.....	239	Blue line prints.....	100	
Asbestos properties near Llano, Texas.....	11	Print frame.....	714		
Ashanti Gold Mines.....	300	Bluestone mine.....	91		
Ashpen, new work at.....	301	Blyth, Charles R. H., death of.....	546		
Assay charges, fire.....	D. C. Livingston.....	468	Boilers, oil and water in.....	286	
Office at Helena, receipts.....	803	Scale.....	486		
Assessment of mining properties.....	C. E. Jarvis.....	210	Boise Basin, Idaho, gold-dredging in.....	J. H. Miles.....	330
Associated Chambers of Commerce of Germany.....	Editorial.....	38	Boleo Copper Co., output for 1911-12.....	643	
Associated mill, Manhattan.....	J. C. Kennedy.....	108	Bolivia in 1911, tin in.....	53	
Associated Northern.....	57	Bolivian goldfields.....	Editorial.....	360	
Association of Commerce and Trade in Berlin, American.....	Editorial.....	38	Bonanza belt east of the Sierras.....	H. C. Cutler.....	833
Atchison, Topeka & Santa Fe Railway Co.....	59	Copper mine of Alaska.....	573		
Atkins, David, Foreign trade and Panama canal tolls.....	378	Bonanza Gold Mining Co.....	125		
Atlas Mining Co.....	387	Mine.....	58		
Atmospheric nitrogen, utilization of.....	19	Mine in Alaska.....	700		
Atmosphere, weight of.....	453	Borax output of California, 1912.....	800		
Atomic weights, report of the International Committee.....	692	Boron Mines Co.....	94		
Auchincruive colliery in England.....	490	Boron researches on.....	629		
Augustin process at Park City, Utah.....	578	Boston copper market.....	22		
Australian Institute of Mining Engineers at Cobarr.....	234	Boston & Idaho Gold Dredging Co.....	330		
Mint reports.....	386	Bottle, self-filling measuring.....	O. C. Smith.....	830	
Railroads.....	Editorial.....	487	Bowie, C. P., History of the Granite Mountain mines.....	466	
Mining laws.....	A. Montgomery.....	141	Braden Copper Co.....	24, 314, 408, 771, 804	
Austin, L. S.....	Wedge mechanical furnace.....	831	Ditto.....	Editorial.....	134
Automatic control of electric hoist.....	F. C. Perkins.....	490	Bradley process.....	636, 643	
Pump starter.....	667	Process at Anaconda a failure.....	606		
		Brakpan Mines, Ltd.....	Company reports.....	32	
		Brandes, Juan Felix.....	Mexican conditions.....	767

"Leading gasoline trucks of the world"

You want the best transportation service and want to know

1. What motor-trucks give it?
2. If so, what size and style?
3. What truck that fits your needs has proved "the best buy"?

You haven't the time or facilities for the necessary study. You want unprejudiced expert advice.

Consult our Engineering Department freely. (You may do it directly or through any of our representatives). You can rely on its judgment because:

1. It has complete transportation data on practically every business.
2. It has exact technical knowledge of motor trucks.
3. Our trucks have proved their value by most years in actual service.
4. Ton sizes: 1, 1½, 2, 3, 4, 4½, 5, 6½, 7½ and 10 tons load capacities. Any type of body (special if needed) built in our own plant.

When you begin to think about transportation equipment, bring your problem to us.

Write our Engineering Department for data on transportation for engineers, contractors and all branches of the mining industry.

## EDITORIAL

CHINA has refused to accept the \$300,000,000 offered her by the international banking syndicate. Loans are often refused, but not usually by the one who needs them.

**D**ISCOVERY of a new Rand near Denver has been enthusiastically announced. As a matter of fact, the fossil placers in Douglas county have been known for some time, but their extent and value remain to be determined accurately. The gold is fine, and how much can be saved is not certain.

**I**LLINOIS petroleum fields have since 1905 yielded 158,-000,000 barrels of oil worth \$103,000,000, according to Mr. R. S. Blatchley, of the State Geological Survey. Mr. Blatchley estimates that over \$20,000,000 has been paid in royalties and perhaps an equal amount in bonuses, labor, and other local expenditures. Of the 20,000 wells drilled in the state 85 per cent have been productive. Such figures give a realizing sense of what it means to 'strike oil' in a corn-growing country.

IT is now announced that the report of the special committee that has been investigating the affairs of the American Institute of Mining Engineers has been completed and is in the hands of the printer. Copies will be distributed among members within a few weeks and will not be held back until the special meeting of the Institute which has been postponed till October 7. In stating the latter we misinterpreted a note from New York. We are glad the report is to be made public in advance of the meeting, since what is most needed is that each member shall have an adequate knowledge of the affairs of the Institute. More members are now taking an active interest in its affairs than at any previous period in its recent past. If the whole membership could be roused to a full realization of their privileges and duties, it would be worth almost any sort of an explosion.

NOTABLE papers upon metallurgy will be features of the program of the Eighth International Congress of Applied Chemistry, to be held in Washington and New York early in September. Curiously enough, no papers upon cyanidation are listed in the preliminary announcement, though a half dozen upon the metallurgy of copper are promised. A paper upon the roasting of copper ores preparatory to leaching, by Mr. Utley Wedge, and another upon the extraction of copper by leaching, by Mr. J. O. Handy, are of timely interest, while Mr. E. P. Mathewson's account of the development of the reverberatory furnace for smelting copper ores, and Mr. Frederick Laist's discussion of the chemistry of the reduction processes in use at Anaconda will be as instructive as interesting. A study of the use of the electric furnace for the smelting of zinc ore, by Mr. F. T. Snyder, should throw light on another present-day problem. Discussions outside the metallurgical field are likely to be helpful in their collateral bearing, and engineers should plan, as far as possible, to be in New York during the first week of September.

**L**IBRARIES that are of value are those which have grown slowly; this is especially true of technical libraries, in which sets of journals and transactions are of first importance. The University of Minnesota has just become the fortunate recipient of what is probably one of the best geological libraries in the United States. It was built up by Mr. N. H. Winchell during the course of his long and active professional career. As editor for many years of the *American Geologist*, he received practically everything of importance published on geology. He supplemented the gifts by liberal purchases of older books, and as a result has brought together a priceless working collection. It is particularly appropriate that these should go to the university in which he was so long an active factor. The collection will be known as the 'Winchell Library of Geology,' and donations and exchanges should hereafter be so addressed. It is hoped that engineers will remember to send copies of papers that they may publish. If one man can afford to give to his profession in this form practically the savings of a life time, certainly the others can afford a little thoughtfulness in return.

**C**ONSTRUCTION of a great mill at the mouth of the 'Newhouse tunnel' at Idaho Springs, Colorado, was part of the original plan of Mr. Samuel Newhouse and his associates. It is gratifying to note that matters have progressed to the point where the Argo Reduction & Ore Purchasing Company, organized by Mr. F. A. Schirmer and others now owning the tunnel, is prepared to build the first unit. Originally the tunnel was planned to drain the mines of Seaton mountain, Quartz, and other famous hills in Gilpin county, and to bring the ores to the south fork of Clear creek for milling. The work has been a success in draining the deep veins and measurably successful in the discovery of ore. It has afforded economical transportation and easy access to the ore; the treatment of the latter has remained to be solved. The ores mined are complex sulphides and have hitherto been treated by stamp-milling and concentration. Tailing losses have been heavy; much heavier than was generally realized or admitted. It is announced that in the new mill, to be erected under supervision of Mr. Arthur H. Roller, cyanidation will be combined with amalgamation. Selection of Mr. Roller to guide the work assures the full benefit of local experience in ore-treatment. The task will be no easy one, but the size of the orebodies warrants large expenditure and careful work, and his professional associates will hope that Mr. Roller's success may be as prompt as his good record deserves.

**S**OUTH AFRICAN mining conditions have been under severe criticism of late. Our Johannesburg correspondent has shown how the great consolidations of companies have not produced the favorable results that were anticipated. In London, Mr. T. A. Rickard has been vigorously denouncing 'phantom profits' and drawing numerous examples from the Rand, and in Johannesburg itself the voice of the critic has been heard. In discussing the matter before the South African Institution of Engineers, Mr. W. L. Honnold took the ground that conditions are not so bad as has been urged. Admitting an average tenor of 27s. 11d. for the past year, as against 28s. 6d. for the year before, he considers this to be due to a scramble for tonnage without regard to grade. While the working cost has apparently increased 5d. per ton, this is thought to be explainable by differences in keeping books. Certain expenses formerly debited to capital account now are charged to operating expenses because additional capital cannot be raised upon satisfactory terms. These views are worthy of especial attention, coming, as they do, from an engineer so familiar with Rand conditions. At the same time it is not

likely that criticism will be stilled. With idle stamps a scramble for tonnage is but natural, and if capital is timid it indicates a profound conviction that conditions on the Rand either are not so favorable as in the past, or that the favorable elements have been persistently overestimated. Mr. Honnold is exactly right in insisting that increased efficiency is the only available means of solving the problems that Rand engineers are now meeting.

### Colleges and Research

Colloids are objects of mystery to most engineers and many geologists, nor, indeed, are they well understood even by those who have devoted much effort to their study. That they must exert considerable influence in ore deposition, hydro-metallurgy, and ore-dressing is generally recognized; the exact nature and scope of their influence is still in doubt. In a recent paper, Messrs. E. Hatchek and A. L. Simon have pointed out that silicic acid gels will reduce gold from its solutions, while Messrs. W. Reinders and C. J. Van Niewenburg have discovered that the presence of gelatin and other colloids markedly reduces the rate of reduction of silver chloride by iron citrate. Evidently the problem is not a simple one. Colloids must be important in the dressing of ores, and especially in treatment of slime, but are little understood, since investigators in metallurgical plants are usually under pressure to secure results of immediate value and have neither time nor opportunity to carry out studies which do not appear to be instantly useful. The early studies of electricity exhibited no indications of proving useful, however, and a large amount of investigation in the field of pure science must be carried on so that the data may be obtained from which to perceive possible applications. In this regard it cannot be denied that many of our mining schools are not living up to their ideals of service and are being led away by a false conception of the work they are properly called upon to perform. The occupying of the valuable time of students at the universities in such matters as the loading of drill-holes and the sharpening of steel, matters which any intelligent and mentally alert man can acquire from a few days' experience when necessary, and which may never be required in the whole of a long and useful life, is certainly not the most efficient use of time, equipment, and opportunity. Much of the most advanced and most useful work is now being done outside the laboratories of the larger schools. Mining schools, as a whole, need galvanizing into renewed activity.

### Colorado Fuel & Iron Company

Dividends, it is announced, will be resumed this month on the preferred stock of the Colorado Fuel & Iron Company. The eight per cent cumulative dividend on this stock has not been paid for nine years, but there is now a surplus such as warrants hope that the arrears may be wiped out. The Colorado Fuel & Iron Company is one of the large institutions of Colorado and the history of the company and the state are woven together. The properties which formed the nucleus of its holdings were originally acquired by Mr. J. C. Osgood, in the interest of the Chicago, Burlington & Quincy railroad, which, it will be remembered, once started ambitiously to build from Denver to the Pacific. Track was laid as far as Lyons, grading went some miles beyond, and rights of way and surveys extended well on to Utah. As part of the plan it was necessary to assure a fuel supply, and Mr. Osgood, a friend and associate of Mr. Perkins, then president of the road, was transferred to Colorado from Iowa, where he had made a success of the Whitebreast Fuel Company and

had opened important mines along the line of the railroad. In Colorado he optioned a number of good coal properties. Then came the famous and bitterly contested strike of the Brotherhood of Locomotive Engineers. The company won the strike, but was so crippled that the plans for Western expansion were abandoned.

Mr. Osgood saw the opportunity and promptly organized a company which took over the options on coal lands and entered actively the business of mining and selling coal. Profits were put into the business, and first coke-making, then iron-making was taken up, and finally, to make a market for the iron, steel mills were built. All this required capital, and, in the end, more than the business itself could supply. A market, too, for the steel was hard to secure. The railroads showed a strange and steady preference for Eastern rails. The inevitable smash came, and with it the long to be remembered and theatrical contest of John W. Gates for control of the company. After the battle of ballots and court proceedings, the company passed into the hands of Mr. George Gould and Edwin Hawley; whereupon the rails were promptly in demand on the Denver & Rio Grande and the Colorado & Southern railroads. Markets have been found, the plants improved, and finally the business has caught up with the company.

The story of this enterprise in all these features is typical of the West. A far-seeing man with eyes on the future overlooks the stones before his feet and stumbles, but in the end the enterprise that he founds makes good and benefits the state. In this instance it is a pleasure to add that Mr. Osgood found profit in the coal business, to which he returned after losing control of the big concern that he founded.

### The Geographic Basis of Industry

The time value and place value of mineral deposits do not always receive the amount of attention they deserve. It is evident that ice, for example, is of no value at the north pole, but is immensely so in the tropics. California's oil deposits were of no value at the time J. D. Whitney examined them, now they are valued at many millions of dollars. The geographic basis of industry is somewhat obscured by the transportability of most products, natural gas being the most conspicuous exception. Wherever it occurs it has stimulated industry by affording cheap fuel, but in many cases even this is not able to counteract the disadvantages imposed by other conditions. Here again the time factor enters. The gas is often allowed to escape, and when conditions change later, and with an increase of population or the opening of means of communication the development of industry is made possible, the gas has in large part disappeared and the fuel supply has been lost. This evanescent characteristic of natural gas was exhibited in the zinc-smelting industry which sprung up in Kansas a few years ago, but as rapidly declined upon the failure of the gas supply. Gold and silver are so valuable and so easily transported that men will seek and win them wherever they may be found, but the less valuable metals have a marked place value. This is well illustrated in the case of iron ores of China, in which country ores of good quality are widely distributed, while coal for smelting is equally available. The native iron industry did not attain any considerable development, however, except in Shansi, where the ores are of poor quality and irregular in occurrence, but are associated with coal which contains a considerable percentage of phosphorus. By its use the natives are able to produce a high-phosphorus pig iron which can be used to make castings of remarkable thinness and perfection of outline, which find their way through the channels of trade even to districts where ores of better quality are found,

but where the coal does not contain phosphorus.

The place factor is not the only one, however, as is illustrated by the brass fabricating industry of the Connecticut valley. This centre of supply for the United States is situated on one edge of the area supplied, if a Hibernianism may be permitted. It is at some distance from its supply of coal, a large item in brass manufacture, and not at the centre of its markets, yet efforts to develop the brass industry in Detroit and other Middle Western cities have not been markedly successful. An important reason for the Connecticut monopoly is the supply of skilled labor; the adjacent population has grown up with complete familiarity with the brass industry and resists efforts to transplant it. In time the labor supply at any point can be trained to the required degree of efficiency, but few companies are prepared to endure the intervening years of no profits. Elsewhere the Colorado Fuel & Iron Company is referred to at some length, and requires no more comment other than to call attention to the apparent paradox, that the easiest place to develop industry is not where none exists, but the reverse. The reason for this is evident, upon deeper reflection. The best place to open a shop is not in the suburbs where none exist, but in the heart of the city where there are many, because everyone desiring to purchase goods, so far as possible, naturally goes to the largest centre of supply because there the largest stock is available. There is always a small local demand in remote districts, but it never increases beyond narrow limits. Unless there is a clearly proved advantage in doing otherwise, the buyer always tends to purchase known brands from large houses which can be relied upon to always have them in stock, make good an occasional defect, and supply the same goods at the same price whenever needed. The business advantage of this to the buyer is so marked that he can afford to pay higher prices than are required to obtain the material without these assurances. Centralization results, and the tendency is to build up industry at the points where it is already established, rather than distribute mineral production and manufacturing enterprises throughout the commonwealth. Thus, though zinc is in brisk demand, the zinc resources of California, which are considerable, are not developed, nor seem likely to be, for the present, at least. Sulphur exists in considerable quantities in many parts of the United States, but the large deposits of Louisiana totally dominate the market. The textile industry of the United States skirts the eastern seaboard, where the streams descend from the piedmont plateau into the coastal plain, thus making water-power available, though most of the wool is grown in the Rocky Mountain states, where water-power is abundant and cheap. No miner can afford to neglect this place factor in the development of mines. The copper deposits of Alaska, Peru, and Chile are large, but their remote situation imposes a handicap which is difficult to overcome. The prospector who wishes to be sure of financial success should discover a 'porphyry copper' near Baltimore or Perth Amboy.

The labor cost of industry is in most instances the controlling factor. Even in the manufacture of so expensive a raw material as gold it more than doubles the cost. The cost of 14-karat gold is 61 to 64 cents per pennyweight, depending upon the market; the cost of working it in San Francisco is 68 cents per pennyweight. Where the raw material is of little value its cost of production frequently sinks into insignificance compared with the cost of utilization. It is often said that the worth of a book is its use, and the epigram is no less true of a metal. The development of the mineral industry is profoundly affected by geographical, chronological, and sociological conditions, and the prospector, to an important degree, needs to take these into account.

# Veta Colorada Mill and Cyanidation Plant—I

By BERNARD MACDONALD

## CONSTRUCTION AND PLAN OF PLANT

*Design of Plant.*—The plant of the Veta Colorada M. & S. Co. at Parral, Chihuahua, Mexico, was designed in 1906, and, in accordance with the general scheme of cyanidation plants of that date, provision was made for separate treatment of the pulp as sand and slime. Orders for the machinery were placed with different manufacturers, and the work of grading the site and construction commenced in 1907. The erection of the mill was then placed under the charge of a superintendent, who made certain changes in the design of the machinery and the arrangement of the cyanidation department, having in view its conversion to an all-sliming plant. Toward the end of 1907, on account of the panic then prevailing, the company suspended all work. Some of the machinery had then reached the ground, some was partly erected, some was *en route*, and a large part was still in the shops in the process of manufacture.

The suspension continued until February 1910, when I was employed to complete the erection of the plant and put it in operation. My instructions implied authority to purchase such new machinery and make such rearrangements and modifications of the previous designs in erection as would be necessary to complete the plant and make it suitable for the then recognized improved system of operation, but to retain and use, as far as possible, the machinery previously ordered. After numerous delays, the machinery reached the ground, was erected, and the plant went into operation in February 1911.

*Source and Character of the Ore.*—The ore supply in sight consisted of the old dumps at the company's mine, amounting to about 50,000 tons, an indefinite quantity in the mine workings which were caved, and an indefinite quantity of custom ore promised from neighboring mines. The average analysis obtained from the dumps and the old workings was:

	Per cent.		Per cent.
SiO <sub>2</sub> .....	69.00	Pb .....	0.03
Fe <sub>2</sub> O <sub>3</sub> .....	3.60	Mn .....	Trace
Al <sub>2</sub> O <sub>3</sub> .....	9.00	Cu .....	None
Zn .....	0.01	Ag (ounces) .....	12.5
Au .....	Trace		

The silver occurred mainly as sulphide in the ore, but subordinately in the form of chloride and bromide.

*Yard and Operating Facilities.*—At the head of the mill a large patio or yard was excavated where the custom, dump, and mine ores are received. Tram tracks from the mine, dump, and railroad terminal converge on this yard, and from it a cross-track was laid down along the entire length of the mill with platforms at the various floor-levels of the mill and cyanidation plant for receiving supplies. The company's business and assay offices, warehouse, carpenter shop, and track scales are built on this yard. The coal-bins are situated immediately below the yard-level, and from them the coal is lowered by gravity tram to the powerhouse.

*Power.*—Electric power generated by steam in a plant on the ground is used for lighting and operating the machinery throughout the mill, with sufficient power to spare for the mining operations. Steam is generated in Heine safety and Fairbanks water-tube boilers, and the electric generators are operated by Harris-Corliss engines, with the generators mounted on the fly-wheel shafts.

*Mill Machinery and Equipment.*—Below the level of the patio is the receiving bin for all classes of ore, from which it is fed over grizzlies (60-lb. rails inclined 42° and spaced 4 in. apart) to the primary Blake rock-crusher, of Australian type with jaw dimensions 12 by 24 in. set to crush to 4-in. size. The product of this crusher joins the ore that passed through the preceding grizzly and gravitates over

another leading to the secondary crusher, which has its bars spaced 1½ in. apart and set on an incline of 42°. The secondary crusher is of the same kind and type as the first, with jaw openings 9 by 15 in. set to crush 1½-in. size. The product from this crusher joins that which passed through the preceding grizzly, all falling into a small steel-hopper collecting bin and automatically feeding upon an upwardly inclined belt-conveyor 16 in. wide and 30 ft. long, which, with a travel speed of 150 ft. per minute, delivers the ore into an open-bottom hopper from which it is spouted to a vertical elevator which carries it up to a hopper-bin set above the cross-conveyor built over the battery-bin. The vertical elevator is of the belt and bucket type, 18 in. wide by 40 ft. between centres with buckets 16 by 7 in. set 18 in. apart. The cross conveyor-belt over the battery-bin is 18 in. wide by 120 ft. long and is provided with an automatic traveling tripper which discharges the ore into any of the compartments of the battery-bin. This bin is flat bottomed, 12 ft. wide, 20 ft. high, and 120 ft. long, partitioned off for each 10 stamps, and has a total holding capacity of 1300 tons with a run-off capacity of 1000 tons. Parallel with the cross conveying-belt a tram track runs over the bin. On this the lime required in the treatment is brought and it is mixed with the ore as the latter is delivered into the battery-bin.

*Sampling Mill Equipment.*—From the stream of ore falling from the collecting hopper at the delivery end of the inclined conveyor-belt two buckets suspended at equal distances apart between two endless chains cut out the sample by taking all the stream for the moment they are passing under the collecting hopper. In operation these buckets are carried over and discharge automatically into a 5-ton bin with 45° bottom, sheeted throughout with steel plate. This is the first cut-out sample. When desired the door of this bin is opened and the contents drawn off and fed to a 7 by 10-in. Dodge crusher set underneath. The crushed product falls on steel plates, where it is shoveled and quartered, the reject sent to the vertical elevator and by it delivered to the battery-bin, while the retained sample goes to a pair of 12 by 12-in. fine rolls, the product from which falls on the floor and is shovel-sampled, the reject being handled as before. The retained sample is then sent through two laboratory grinders in sequence, being shovel-quartered after each grinder and the final sample put through an Iler pulverizer, the entire product of which is quartered on oil-cloth and sent to the assay office. The cutting-down floor underneath the sampling machinery has an area of 12 by 20 ft. and is sheeted with ¼-in. steel plate throughout.

*Stamps and Dewaterers.*—From the battery-bin the ore is fed to the stamp-mortars by suspended Challenge feeders; the mortars weigh 10,500 lb. and are bolted to concrete foundations with a ¼-in. rubber sheet intervening. The stamps, of which there are 80, weigh 1050 lb. each and are set to drop 7½ in. 104 times per minute. The depth of the discharge is 4 in. above the dies, about 1 in. above the ore-bed. The ore is crushed in the precipitated solution returned from the zinc-boxes and fed to the mortars with the ore in the ratio of 8 tons to 1 ton of the dry ore. Rectangular screens of the equivalent of 14 to 16 mesh were used, and 35% of the pulp issuing from the mortars would pass 200 mesh. The crushing capacity is about 5 tons per stamp.

On issuing from the mortars, the pulp from each 20 stamps is piped to a 4 by 4-ft. dewatering cone which overflows 20% of the battery water with a varying quantity of 200-mesh pulp in suspension, this overflow being piped direct to the Dorr thickeners. The underflow pulp from these dewatering cones, containing between 6 and 7 tons of solution to 1 of solids, is carried in floor (cement) launders to a collecting tank from which it spouts to two belt-bucket elevators which lift and deliver it to a dis-

tributing box set 20 ft. above the floor. From this box it is equally distributed and carried in three distributing pipes to three duplex Dorr classifiers each 5 by 15 ft. The slime portion of the pulp classified by these, of which about 80% goes through 200 mesh, goes direct to the Dorr thickening tanks, while the sand classification is distributed in pipes to the scoop-boxes of the tube-mill.

classifiers, where it is received for re-classification along with the battery pulp underflowing from the dewatering cones mentioned above. Thus, the classification of the pulp, with the exception of that overflowing from the dewatering cones, is effected in a closed circuit and results in a slime classification going to the thickening tanks, 80% of which is of -200 mesh.

VETA COLORADA, GENERAL VIEW.

AGITATING TANKS AND FILTERS.

*Fine Grinders.*—There are five tube-mills set together, each 5 by 14 ft., operated at from 27 to 30 revolutions per minute. The discharge from all these mills is received in a cross-launders set on 10% grade, which in turn discharges into the boots of three belt-bucket elevators, two of which are kept in operation and one held in reserve. These elevators raise the tube-mill product to a distributing box from which it is led back through pipes to the Dorr

*Pulp Thickeners.*—The three Dorr thickening tanks which receive the classified slime are 36 ft. diam. by 12 ft. high, and in them the collecting rabblers are geared to make one revolution every seven minutes. The clear solution overflowing from these tanks goes to a 12 by 36-ft. sump-tank, from which it is pumped back to the two head-supply tanks (set 30 ft. above the batteries), each of which is 12 ft. high by 36 ft. diam. When this sep-

arated solution from the thickening tanks becomes sufficiently charged with silver to warrant precipitation, provision is made to pipe it to a filter-press through which it flows by gravity and is clarified and then goes to the zinc-boxes for precipitation.

*Dilution and Elevation of the Thickened Pulp to the Treatment Tanks.*—The thickened pulp underflow from the thickeners, containing about  $1\frac{1}{2}$  of solution to 1 of solids, is piped to the boots of two elevators by which it is raised to the agitation tanks. As this pulp is delivered to the elevators it is diluted by precipitated solution returned from the zinc-boxes mixed with the wash-water from the filter-presses to the consistence of 2:1, which was found to give the best results in treatment.

The two elevators lifting to the agitation tanks are of the belt-bucket type, 55 ft. between centres, the belts being 24 in. wide. One of these elevators is in constant use and the other held in reserve. The elevated pulp is received in a box, at the head of the elevators, fitted with a cover and false bottom of wire screen, into which the cyanide and lead acetate required to bring the solution in the pulp up to treatment strength are placed every hour, and are gradually dissolved by the splash of the discharging pulp. Provision is made for piping the pulp from the receiving box to any of the agitation tanks for treatment by the individual-tank process, or for delivery into the first of the series of agitation tanks for treatment by the continuous process as desired. In the latter case, which was permanently adopted after extended trial, provision is made for the pulp to flow from tank to tank and be drawn from the last of the series to the filter-presses.

*Agitation Tanks.*—The treatment or agitation tanks consist of a battery of six tanks which contains one standard Pachuca tank, 15 ft. diam. by 45 ft. high, and five Parral tanks 25 ft. diam. by 42 ft. high, having holding capacities of 83 and 250 metric tons, respectively, of 2:1 pulp. The agitation is effected by compressed air in both tank systems; in the Pachuca tank in the usual way through a central lift-pipe of 16-in. diam., and in each of the Parral tanks by four lift-pipes each of 12-in. diam. set equidistant from each other and  $2\frac{1}{2}$  ft. from the interior side of the tank. The discharge ends of the lift-pipes in the Parral tanks are set horizontal and so directed that the discharging pulp flows in the same direction as segmental cords with respect to the interior side of the tank. The force of the discharge pulp sets up and maintains a rotary flow in the entire pulp charge from top to bottom of the tank. This rotary flow preserves the solution and solid constituents of the pulp charge in proper proportional mixture and prevents the settlement of the pulp on the bottom of the tank into dead accumulations.

*Filter-Presses.*—When the treatment cycle in the agitation tanks is completed, the pulp is drawn off to a battery of Kelly filter-presses, of which there were 8 operated hydraulically from a central platform in two units of 4 each. Each of the presses is 5 by 15 ft. and contains 13 leaves having a total filtering area of 1500 sq. ft. The Kelly filter-presses, and the excess-pulp, precipitated-solution, and wash-water tanks are shown in the foreground in the illustrations.

The operating cycle and results are as follows: Density of pulp received, 1.26; percentage of -200 pulp, 80; time charging and building cake, 13 to 28 minutes; expelling surplus pulp, 2; washing with precipitated solution, 10; washing with water, 3; drying with air, 3; discharging cake, 10; total cycle, 40 to 50 minutes; thickness of cake,  $\frac{5}{8}$  to 1 in.; moisture in discharged cake, 15 to 18%; assay difference between washed and unwashed cake, 3 grams silver.

*Disposal of the Cake.*—The cake discharged from the filter-presses falls into a V-shaped box sheeted with steel plates which extended transversely underneath all the presses. In the bottom of this box is a right and left-hand screw-conveyor which works the discharged cake, mixed with water, to a central box where it is cut up with a chopper made of spikes inserted in a hub to the shaft

of the screw-conveyor. As the cake is being chopped it is struck by a 1-in. stream of water under pressure-head of 200 ft. and thus mixed and diluted, it passes through the tailing launder, set on grade of 12%, to the tailing dump.

*Manipulation of the Filtered Solution.*—The filtered rich solution from the presses is collected in a launder underneath, from which it flows in a pipe to two collecting tanks each 10 ft. high by 20 ft. diam., from which it flows to five clarifying boxes, each having five compartments. These boxes are of the zinc-box type with baffle partitions between the compartments and 3 by 15 ft. over all by 5 ft. deep. Leaves of cocoa matting are placed in the compartments and spaced 2 in. apart. The outflow from these boxes is piped to two storage tanks, each 36 ft. diam. by 10 ft. high, from which the flow to the zinc-boxes was so regulated as to be continuous and uniform.

*Measuring the Solution.*—These tanks were designed to be used alternately in feeding the zinc-boxes; when one is feeding the zinc-boxes the other is receiving the solution flowing from the clarifying boxes. With floats connected by ropes run over sheaves to weights which rise and fall along vertical recording boards in the zinc-room like those of railroad tanks, the zinc-room man is enabled to record the cubic feet or tons of solution that passes each shift of 12 hours through the zinc-boxes.

*Sampling the Solution.*—The solution coming to the zinc-boxes is sampled by a drip-cock tapped into the main delivery pipe, and thus the tonnage of solution going through the zinc-boxes, and its assay value, is recorded. In like manner the main pipe carrying the precipitated solution from the zinc-boxes to the precipitated solution sump-tank is provided with a drip sampler, the assay of which subtracted from the head sample shows the amount precipitated in the boxes.

*Return of the Solution.*—The sump-tank is 10 by 36 ft. and the precipitated solution received in it is pumped back to an intermediate sump-tank from which the amount required for diluting the pulp going to the elevator lifting to the agitation tanks is supplied, the amount not needed for this purpose being pumped back to the supply-tanks at the head of the mill.

*The Precipitation Room.*—The precipitation of the rich solution is effected by zinc shavings in 11 zinc-boxes, each box having five compartments, 3 by 3 by 3 ft., for the zinc shavings and having a total holding capacity of 1331 cu. ft. of shavings. As a rule only four compartments of each box were charged with shavings, since the precipitation is complete in four of the compartments. From the bottom of these compartments, which are pyramidal in shape, a pipe with stop-cock is provided for the discharge of precipitate during the clean-ups, which are made weekly. The precipitate, with the associated zinc shorts, as discharged from the zinc-boxes, is flushed and brushed through half-round steel launders to a collecting sump-tank provided with screen trays at its top, through which the precipitate passes. The zinc shorts, + 60 mesh, in the precipitate are caught in the screening trays, where they are scrubbed and washed and removed from time to time, and returned to the head compartments of the zinc-boxes, where they are gradually consumed by the flow of the rich solution entering for precipitation.

*Filter Pressing the Precipitate.*—From the sump-tank the precipitate is pumped through a Dehne press, 8 by  $2\frac{1}{2}$  ft., with 30 leaves having a total filtering area of 650 sq. ft. The effluent solution from the precipitate press goes to the zinc-boxes, where any escaping precipitate is caught in the zinc shavings.

*Fluxing and Drying the Precipitate.*—When the cake of precipitate is built in the press it is discharged into a shallow box run on flat wheels underneath the press. In this box the precipitate when sampled for moisture is weighed, mixed with the required fluxes, and filled into iron trays 30 by 10 by 4 in. and placed on the shelves of a steam-drying cabinet. This is a closed cupboard-shaped box made of  $\frac{3}{16}$ -in. steel plate, measuring 8 by 6 by 3 ft.,

with shelves made of 1¼-in. pipe extending from 3-in. headers at the sides, through which low-pressure steam generated in an upright 5-hp. boiler circulates. The cabinet can be securely locked and serves as a safe for the precipitate until needed for melting.

*Melting and Sampling.*—For melting the precipitate there are three Steele-Harvey tilting oil-fired furnaces, containing No. 275 Monarch crucibles, into which the dried and fluxed precipitate is charged and the melt effected. The bars weigh from 70 to 75 lb. avoirdupois each, and are sampled by boring at opposite corners of both sides ⅝-in. holes to the depth of 1 in. The silver in the bars ranges from 850 to 900 fine.

*Air-Compressors.*—An Ingersoll-Rand, type 10, air-compressor generates the compressed air used for agitation, filter-pressing, and air lifts. This compressor has a seal-level displacement of 1000 cu. ft. of free air per minute, and at the plant, 6000 ft. elevation, about 80% efficiency is obtained. The pressure carried for this plant is 30 lb. per square inch.

*Motors.*—Westinghouse motors are used throughout the plant, the type being 3-phase, 25 cycle, 440-volt, alternating current. Their number, where used, rated horse-power, hours run per day, and power consumed is as follows:

No.	Used to run	Rated hp.	Con- sumed hp.	Run- ning hr. per day.
1	Two Blake crushers and belt bucket-elevator .....	50.0	49.7	10
1	Cross conveyor-belt .....	5.0	2.7	10
1	Sampling mill machinery...	15.0	5.0	8
4	Stamp batteries, one to each 20 stamps .....	200.0	198.8	24
3	Three Dorr classifiers.....	5.0	3.0	24
1	Five pulp elevators.....	20.0	12.7	24
5	Five tube-mills, 40 hp.....	200.0	155.0	24
3	Three Dorr thickeners.....	3.0	1.0	24
1	One belt bucket-elevator to treatment tanks .....	10.0	4.2	24
1	Ribbon pulp conveyor.....	10.0	5.3	20
1	Triplex pump returning solution .....	20.0	16.8	20
1	Triplex pump returning solution .....	15.0	7.6	20
1	Triplex pump returning solution .....	7.5	2.0	20
1	Pump and lathe in zinc room .....	5.0	5.7	10
1	Ingersoll-Rand compressor..	100.0	83.3	24
1	Motor generator .....	40.0	32.0	24
	Lighting (417 hp-hr), from plant .....	17.4	17.4	12
28	Totals .....	722.9	602.4	

From the table it will be seen that the 28 motors connected with and driving the milling machinery, have a total rated capacity of 722.9 hp. and that these motors when carrying the full load of all machinery running together, including the pro-rated lighting, consumed 602.4 hp., 83% of the nominal power of the motors, or say, 1.5 hp. per ton of milling capacity.

(To Be Continued.)

COMPLETE returns of the coal production in the states of the Rocky Mountain region in 1911 have been received by E. W. Parker, of the U. S. Geological Survey. The eight states included, namely, Colorado, Idaho, Montana, Nevada, New Mexico, North Dakota, Utah, and Wyoming, produced in 1911 a total of 26,044,387 short tons, valued at \$40,098,747. Although no coal was produced in Nevada in 1910, the output of the seven other states was 28,857,413 short tons, valued at \$43,776,715, indicating a decrease in 1911 of 2,813,026 short tons, or 9.7% in quantity, and of \$3,677,968, or 8.4% in value. This decrease was due to the resumption of mining in the Mississippi Valley states, the idleness in which, caused by the strike in 1910, resulted in extraordinary demand on the mines of most of the Rocky Mountain states. The total number of men employed in the coal mines of the Rocky Mountain states was 33,783, who worked an average of 219 days, against 34,652 men for an average of 245 days in 1910.

# The La Fortuna Mine

By F. J. MARTIN

During the early nineties a large number of men were on the desert of southern California, Nevada, and Arizona, prospecting for placer gold. A dry-washing machine had been invented that seemed to answer the purpose of a rocker or long-tom. And although nothing particularly good in the way of placers was found, the excitement proved to be the means of a number of good lode mines being discovered; among them the Yellow Aster in Kern county, California, and the La Fortuna in Yuma county, Arizona.

As is well known, few live springs of water exist on the desert, especially in Arizona, but nearly every mountain range contains natural depressions which are filled by summer and winter showers. These 'tanks' vary in size and retaining capacity. Those filled with coarse sand and gravel are less liable to be drained by wild animals and evaporation. It was at one of these tanks that three prospectors, Halbert, Albert, and Thomas, had their camp in the winter of 1894, on the western slope of the Gila City range of mountains, about twenty-three miles southeast of the town of Yuma. They had been there but a few days when Thomas found some good-looking 'float' in one of the main washes, and it did not take him long to trace it to the croppings, which were quite prominent, and rich. Pieces broken at random from any part of the vein, when ground and panned, showed a long string of colors, some of which were as large as wheat grains.

It is remarkable that no one had ever taken the trouble to investigate those croppings before, since a well-beaten smugglers' trail led by not a hundred feet away. While the smugglers were intent on beating the Mexican or United States government out of a few dollars, there was an unsuspected fortune staring them in the face.

It is wonderful how news of a discovery spreads. One may be on the desert prospecting weeks at a time without meeting a soul, but let a rich prospect be discovered, and before he is aware of it, the place is swarming with men. I have seen notice of location of valuable claims written on cigarette papers, about one and a half by three inches in size, the locators having rushed pell-mell to the new district with nothing but some tobacco and cigarette papers, the inevitable article always in evidence on the southern desert. As soon as the news of the find reached Yuma, the recorder, a man named Pool, sent word to his friend, R. M. Straus, who was at the Haraqua-Hala mine during its palmy days and who had requested Pool to keep him informed of anything new. Straus lost no time in getting on the ground, and, being well and favorably known, had no trouble in securing a bond on the property at a price of \$150,000. He took the matter to C. D. Lane, of Utica mine fame, and persuaded him to go and examine the property. It proved to be a case of love at first sight with Lane. The locators had sunk a hole about 30 ft. deep by this time, and had shipped a carload of selected ore to a smelter and received over \$70 per ton.

Mr. Lane decided to develop the property immediately, and a force of men was put to work. The 'tank' water by this time having all been used, water had to be hauled from Blaisdell station, on the Southern Pacific railroad, a distance of 14 miles. The railroad company charged 10c. per gallon for this, having brought it from Sentinel, 80 miles distant, in tank-cars, and stored it in a cistern built of concrete on the ground. The railroad company maintains these cisterns at all their dry stations and section-houses, and prospectors are welcome to all they can make use of, for themselves and burros, free of charge. Several months after Lane became interested, I visited the camp. Much sport was being made over the scarcity and expensiveness of the water, it being sold in camp at 25c. per gallon. The supply ran low several times, and the men claimed that they had to wash in left-over soup, after which the soup was used for drilling. They said

the soup didn't always have the first use—but all agreed that the last use was for drilling.

When the shaft, which was sunk in the centre of the main lens, had reached a depth of about 200 ft., Mr. Lane decided to buy and equip the property. A 20-stamp mill was erected, each stamp weighing 1450 lb.; a compressor and hoist were set up with four 80-hp. boilers; shops, store, boarding-house, and buildings were built, and a good well was sunk at the Gila river, a pumping station built, and a 4-in. screw pipe-line laid to camp. This furnished an ample supply of fairly good water.

The vein occurs in the middle of a large belt of amphibolite schist, which extends across the mountain range a distance of fully ten miles, dipping under the desert on both sides, and it is about three miles wide, gradually merging into a mica schist at either side, and from that into granite. The beds of this schist lie at an angle of about 60°, the strike being east and dip south. The quartz differs from any I have ever seen. It was mostly rose colored, and the best of it was glassy and transparent, slightly tinged with green in places, although it contained no copper. It was the freest milling ore I ever saw; and a most remarkable feature was that the ore became freer from base metals with depth, although it contained very little near the surface. The vein follows the strata, both downward and lengthwise. Near the surface the ore was in short lenses, being about as broad as long. The largest discovery lens was about 30 ft. wide and 40 ft. long; but gradually this changed until at the 500-ft. level the ore formed one continuous pay-shoot about 3½ ft. wide and 500 ft. long. Many faults were found, varying in amount of throw and in direction. The greatest movement, beyond which the ore was again found, was 600 ft. Finally the main fault was encountered and the vein was not found again, although the line of the fault was followed from a little below the 1000-ft. level, where the ore was finally cut, to the 2000-ft. level. By this time all the ore had been worked out, and the company did not care to levy assessments to prospect further. I favored another effort, since shortly before closing the mine I discovered what I believed to be the main fault, in the foot-wall of ore then followed, and concluded the prospecting had been conducted in a wedge-shaped piece of country rock which had been shoved up from below. I hope some day to interest capital in further prospecting on the foot-wall or what I believe to be the main fault. The vein was as strong and the ore as good where faulted and lost as at any point above.

The last sample taken from the lowest point assayed \$40 per ton. This is almost three times the general average of all the ore treated. Waste finds its way into all mills, which increases the tonnage but reduces the value. At the Fortuna a total of 180,780 tons was milled; it yielded on the plate \$2,505,931. A considerable quantity of the tailing was lost by cloudbursts washing it away, but that treated by cyanide returned \$377,144. The total gold recovered was \$2,883,075, which gives an average value of \$15.94 per ton of all ore worked. The general store, operated in connection with the mine, made a profit of \$30,000. The cost of mining, milling, and cyaniding was \$1,377,375. This includes prospecting for the lost vein, and the upkeep of plant. The plant cost in the neighborhood of \$200,000, and \$155,700 was paid to the locators, Thomas at the last moment insisting on getting \$5000 for finding the vein, and the contract making it expedient to pay this. The locators also received \$100 per month during the life of the bond, seven months. The balance, \$1,180,000, was paid out in dividends.

When Mr. Lane decided to buy and equip the property, he organized a company and invited numbers of his old employees and friends to join him on equal footing with himself, guaranteeing them against all losses. He considered himself entitled to a bonus of \$5 for every dollar he had risked in proving the property a safe investment, and all stockholders agreed in this. This bonus amounted to \$75,000. All those invited to join took advantage of this offer, with the result that many a little 'nest-egg' was

laid by and several good men were enabled to get upon their feet.

It is a notorious fact that almost all the good mines on the desert have been found by drunkards, who sold for a shoestring to get quick money to go on a spree, or if they happened to get a fortune for their find, it only meant a more protracted spree. There have been exceptions to this rule, and the La Fortuna, which was happily named, was a striking one. Everyone in any way connected with the mine did well. Even Pool, the recorder, received \$5000 for his small pains in having notified his friend Straus of the find. Thomas bought a walnut grove near Santa Ana, Albert went back to France, Halbert engaged in the ice business, the stockholders got back over \$5 for every \$1 invested, and all blessed the day the La Fortuna was found.

## Gold-Mining Companies in Russia

Russian and foreign gold-mining companies operating in Russia and Siberia, with the capitalization of each, are listed by the *Mining Journal*. The list, with some additions and corrections, is as follows:

1. Russian Gold Co.....	rubles	3,375,000
2. South Urals Gold Co., 'Rossia'.....	"	300,000
3. North-Eastern Siberian Co.....	"	3,000,000
4. Troitsk Goldfields, Ltd. (Katchkar district, Orenburg) .....		£625,000
5. Tushetushanovsky and Tzentzen-shanovsky Ainaki (Mongolia).....	rubles	1,800,000
6. Alexandrovsky Gold Co.....	"	80,000
7. Amur Gold Co.....	"	3,000,000
8. Draga (Dredge) Gold Co.....	"	500,000
9. Transural Mining Co.....	"	4,500,000
10. Société Anonyme des Mines d'Or du Katchkar (Orenburg government) ..	"	4,500,000
11. Industrial Co. ....	"	7,000,000
12. Lena Gold Mining Co.....	"	11,100,000
13. Lena Goldfields, Limited.....		£1,405,000
14. Orsk Goldfields, Limited .....		£920,000

IN Durango, Mexico, about 50 miles northeast of Cedros, a large vein carrying cerussite occurs. It is 50 ft. wide where cut through by a small creek; below this it lies on a side-hill slope, dipping about 45°, and exposed by erosion for 1500 ft. in length and 500 to 1000 ft. on the dip. There is an old inclined shaft, 50 ft. deep, at the point where the creek cuts it; the ore is there much oxidized, some of it assaying 20% lead, \$1.50 gold, and 5 to 8 oz. silver per ton; occasionally a little zinc occurs. The country rock is andesite. The mine is on the east side of the Coast range, close to the foothills of the Sierra Madre, and quite inaccessible. A few miles north of it is an old trail leading up into the mountains which can only be followed in places where hewn out of the rocks. The trail is in a mild unsettled section, and it is possible that it leads to the lost Tiopa mine which so many have hunted for.

IRON ORE deposits at Gogo Soco, in Minas Geraes, Brazil, are to be developed by the Gogo Soco Syndicate, Ltd., of England.

# Industrial Lead Poisoning

By JAMES O. CLIFFORD

## INTRODUCTION

There are few matters worthy of greater consideration by American lead-mining and smelting men than preventive measures to insure to employees freedom from plumbism. The subject has been given attention by lead pigment manufacturers, but mining and smelting companies have remained indifferent. Prior to the year 1900 the same condition existed in Europe, but a thorough investigation of the danger from plumbism to which lead-workers were subjected led to governmental legislation. The regulations imposed by European nations in this connection have been attended by highly gratifying results. Experience having pointed the way, there is reason to believe that similar legislation in America would prove equally beneficial. Employers can, however, anticipate such action by affording their employees all necessary protection. In two or three states statutes have been enacted regulating the conditions under which laborers may be employed in the lead industries. While the effort to protect employees by state legislation is highly commendable, it is not comparable to federal supervision.

## PLUMBISM

Lead is a subtle poison. Of all industrial poisons it is the most productive of ill health. Some persons are more readily influenced by it than others; there is, however, no special type of constitution which is the more likely to be influenced thereby, nor is there any racial predisposition. Generally speaking, young persons are more susceptible to its influence than those of maturer years. Alcoholic excess and the use of tobacco have been conclusively demonstrated to be harmful factors in predisposing to plumbism.

Primarily, plumbism is a question of elimination of the lead taken into the human body failing to keep pace with its absorption. The repeated entrance of lead into the system in minute quantities over a lengthened period of time is more productive of harm than the absorption of that element in larger doses upon only a few occasions.

There is no specified length of time of exposure necessary to produce plumbism. Physical condition of workmen's health and other general circumstances determine this factor. At lead mines and smelters, where even ordinary precautions are not taken by either employers or employees, it is not unusual for laborers to evidence symptoms of the disease within a week following their engagement. Acute lead colic is often induced within periods of from two to six weeks. Recurrences of plumbism in employees engaged in lead mining or smelting are frequent; instead of conferring immunity, one attack of poisoning prepares the way for another.

Lead is dangerous, whether in the solid, liquid, or gaseous form. The solubility of lead compounds by the secretions of the body is an index to the development of plumbism. By experiment it has been determined that, in order of their solubilities by the stomach and the respiratory organs, lead oxide is the most soluble, followed by lead carbonate, lead sulphate, lead sulphide, and metallic lead, in the order given.

Lead enters the body through the skin, the respiratory organs and the alimentary canal. Of these the skin is the least important. Lead dust or fume, carried into the bronchi, trachea, and lung cells is there deposited, and by the influence of heat and moisture the lead compounds are moistened by fluids rich in carbonic acid coming from the lungs and converted, first into carbonate, and subsequently into bicarbonate, in which form it is fairly soluble. The entrance of lead through the alimentary canal is, next to the respiratory organs, the most common mode of entrance. Lead dust, caught in the mouth, is partly dissolved by the saliva and swallowed. Entering the stomach,

the lead is acted upon by the gastric juices where the lead dissolved is converted into a soluble and diffusible chloride, in which form it is readily absorbed by the blood. While the entrance of lead through the skin is not so important as the two modes above outlined, it can readily be absorbed through the pores of the skin, exposed membranes (cuts, bruises, and sores), and the inner surface of the eyelids.

## SYMPTOMS

One of the earliest signs of plumbism is the peculiar anemic appearance of the victim. This is accompanied by a disagreeable metallic taste in the mouth, a feeling of sickness, with tendency to vomit. The tongue is coated, and the breath fetid. Disturbed digestion, poor appetite, obstinate constipation, and a sense of fatigue disproportionate to the amount of energy expended is also complained of. At about this period there is developed a severe pain in the abdomen, accompanied by vomiting. Swelling of the gums and severe headaches often accompany the above symptoms.

Upon examining the victim's gums a persistent blue line is observed close to the teeth. If the patient is toothless the blue line is absent. Occasionally the surface of the tongue shows a similar coloration. The urine is scanty and frequently contains traces of albumen. On chemical examination of any vomit lead will be detected. As a rule the saliva of the patient contains no sulpho-cyanate of potassium. On the addition of a few drops of ferri-perchloride solution to the saliva of a healthy person a brownish red ring will be seen where the two fluids meet. This characteristic is absent in the saliva of a lead colic patient.

The blue line on the gums is, when accompanied by other symptoms, a valuable aid in diagnosing plumbism. Too much importance cannot be attached to this blue line, however, as similar blue lines often develop on the gums of persons who have taken, internally, large doses of bismuth, or have used a bismuth mouth-wash for ulceration of the gums and mucous membranes of the mouth. Also, there is occasionally observed on the gums of persons using carbolic acid solutions, or charcoal tooth-powder, a bluish black line. On the gums of copper-workers a bluish green line is apparent. In many instances a blue line on the gums of lead-workers is present when other symptoms are absent. The reverse of this is correspondingly true. In consequence of the foregoing, the presence of a blue line on the gums is not, in the absence of other symptoms, a conclusive indication of plumbism.

## EFFECTS

For a varying period there may be an elimination of lead from the body which bears a constant ratio to its absorption. It is when a check is placed upon elimination that there commences a storage of the poison. Plumbism is not always a question of any stated amount of lead being present in the body. The reason for this is that some are more susceptible to its influence than others; and besides, lead may, by destroying the functional activity of the eliminating organs, favor the retention within the body of poisons generated by the individual himself, autointoxication, so that the patient suffers, or dies, from a mixed form of toxemia.<sup>1</sup>

The effect of lead varies with the constitutions of the individuals attacked thereby. There cannot be any fixed rule. Common results of plumbism are: lead blindness; temporary loss of hearing, smell, and taste; stimulation into activity of neurosal tendency, to which the patient is hereditarily or otherwise predisposed; loss of teeth, accompanied by serious ulceration of the mucous membranes of the mouth; continuous headache, dizziness, sleep-

<sup>1</sup>Oliver, 'Gulstonian Lectures.'

lessness, tinkling in the ears, and weakening of will and intellect; chronic constipation; and paralysis of the hands and feet.

Another item of interest and importance is the length of time lead may remain in the body. Years after the symptoms of poisoning first show themselves, and apparently have disappeared, there may be fresh signs of intoxication, even though the individual had not been exposed to the absorption of lead following the first instance.

The main channels of elimination of lead from the body are the kidneys and intestinal canal. During the period of elimination, which may extend over many years, these eliminating organs often undergo structural changes, and in view thereof may induce death either as contributory or immediate causes.

From the foregoing paragraph it might be of interest to state that as the result of numerous post-mortem examinations of victims of plumbism, that disease was determined to have been either a contributing or immediate cause of death, depending upon the individual case. In the instances mentioned, the immediate causes of death were as follows: acute plumbism; chronic plumbism; acute gastritis; chronic gastritis; apoplexy; Bright's disease; paralysis; heart disease, and cirrhosis of the liver.

#### PREVENTION

In the prevention of plumbism cleanliness of the individual and work places cannot be too strongly insisted upon. Lavatories with a sufficient supply of hot and cold water should be furnished by the employer and daily bathing encouraged. In dusty atmospheres, respirators should invariably be used. Food should not be eaten at any time or at any place until after the face and hands have been washed, and the mouth and throat rinsed thoroughly with an alkaline mouth-wash. In this connection a mouth-wash of 0.2% solution of sulphite of soda will be found highly beneficial. The use of alcoholic liquors and tobacco should be prohibited. Employees should never begin the day's work without first having had food. Perfect ventilation should be established in all places where there is danger of dust or fume. Employees should take care to keep the bowels open. Proper foods, rich in fats (and in this milk is included) have a preventive value beyond question. The most effective protectives against the disease are cleanliness and sobriety. Medical examination of employees once or twice monthly should be made compulsory. Some companies provide tabloids containing 5 grains of hyposulphite of soda to be taken by employees once daily.

#### DANGER TO EMPLOYEES

**Lead Miners.**—There are comparatively few miners who have worked in lead mines for any considerable period of time that have not suffered from plumbism. The majority of cases have been the acute form, but there are numerous examples of the effects of chronic poisoning. In lead mines (or in other mines where lead is a constituent of the minerals mined) great danger of plumbism to miners is occasioned by the dust given off from the ore and which they cannot avoid inhaling. This condition is intensified in poorly ventilated mines by reason of the fumes from the powder used in blasting and the smoke from candles. In consequence of the two latter evils, miners often suffer from fibrosis—a hardening of the lung tissues due to mild inflammation of the supporting texture of the lungs. Impure drinking water, poor food, and unsanitary living quarters are harmful factors. Alcoholism and the absence of cleanliness among certain classes of miners, are important contributory influences. In small mining camps medical attention is not always available.

**Lead Smelters.**—The danger from lead-smelting operations is not confined to the immediate property. The dust and fume liberated from smelter stacks are a source of danger to inhabitants in the immediate vicinity of the plant unless the diffusion of the gases therefrom is complete and the quantity of lead and other harmful components relatively low.

**Calcining and Reverberatory-Furnace Workers.**—The main danger to employees operating either of the two furnaces named lies in the drawing off of the charge. It is not unusual to note that, in drawing the furnace charge, workers often suffer from smothering, resulting from the fumes and dust given off by the hot or molten material.

**Blast-Furnace Workers.**—The dangers incident to lead-smelting in blast-furnaces are, the dust given off when placing the charge, and the inhalation of fumes escaping from the charging-floor, lead-well, slag tap-hole, open hearths, matte and slag cars. Slags vary in melting point from 1000 to 1500°C., whereas the melting point of lead is 325°C. Under these conditions the danger from lead vapors given off is apparent. From analyses of fume escaping from molten lead and molten slag it has been calculated that in eight hours a man might breathe seven grains of lead.<sup>2</sup> The danger from dross raked from lead melting-pots and deposited on the floor to cool is a source of great danger.

**Zinc Smelters.**—According to Ingalls:<sup>3</sup> "Fumes of zinc oxide appear to be quite harmless to human beings, but when the ore subjected to distillation contains lead there is danger of poisoning by the fumes of that metal." In view of the foregoing, it might be of interest to state that, while the lead content of the average grade of zinc ores subjected to distillation by American smelters is comparatively low (averaging from 1 to 8% Pb), it is not unusual to treat ores containing as high as 20% lead.

**Refiners.**—While electrolytic refining of silver-lead bullion has superseded, to a great extent, the Parkes, Pattinson, and other older methods, the latter, where used, are a source of great danger to employees.

#### EUROPEAN GOVERNMENTAL REGULATIONS

In Europe laws have been enacted by several nations relative to the protection of employees engaged in the lead industries. Of especial interest are the regulations imposed by the British, German, and French governments, excerpts from which are given herewith.

**Great Britain.**<sup>4</sup>—Employers shall, (a) provide respirators and overall suits for the use of all persons employed in cleaning the flues, and take means to see that same are used; (b) they shall arrange that no person be allowed to remain at work more than two hours at a time in a flue (a rest of half an hour before re-entering will be deemed sufficient); (c) they shall provide sufficient bath accommodations for all persons employed in cleaning flues, and everyone so employed shall take a bath before leaving the works; (d) they shall provide washing conveniences, with a sufficient supply of hot and cold water, soap, nailbrushes, and towels.

In cases where co-operation of the workers is required for carrying out the foregoing rules, and where such co-operation is not given, the workers shall be held liable under Section 2, Workshop Act of 1891, which is as follows: "If any person who is bound to observe any special rules established for any factory or workshop (in which is included smelters) under this act, acts in contravention of, or fails to comply with, any such special rule, he shall be liable on summary conviction to a fine not exceeding £2."

**Germany.**<sup>5</sup>—The main requirements in this country are:

1. The rooms wherein lead is roasted, raked out, and worked, where lead containing silver is ladled off, where oxides and other compounds are made \* \* \*, also where zinc scum is distilled, must be spacious, high, and so arranged that there is sufficient and continuous change of air; (b) the rooms must be provided with a level and solid floor, permitting of an easy removal of dust by wet methods; (c) the walls must have a smooth surface so as to prevent accumulation of dust, and must be washed or whitewashed at least once a year. In roasting sheds with wooden walls this regulation is not enforced.

<sup>2</sup>Bulletin de l'Inspection du Travail, 1906.

<sup>3</sup>'Metallurgy of Zinc and Cadmium,' page 631.

<sup>4</sup>Regulations and Special Rules in Force, January 1908.

<sup>5</sup>Regulations of the Imperial Chancellor Concerning Erection and Management of Lead Smelting Works, June 16, 1905.

2. For workmen engaged at the furnaces and melting-pots there must be a sufficient supply of drinking water in a convenient and completely protected place. In the neighborhood of the furnace there must be arrangements for spraying the ground. The floors of all places mentioned in rule 1 are to be cleaned once a day in the moist state.

3. Lead ore and smelted products containing lead, if not moist, are to be crushed in machinery so constructed that dust will, as far as possible, be prevented entering the work-rooms. This does not apply to the roasted material removed from the converters. Sacks in which lead ore or lead products have been packed must only be cleaned in closed apparatus.

4. Materials containing lead oxides, if dusty, must be moistened before being mixed with other materials preparatory to being placed in the furnace.

5. Dust, gases, and fumes escaping from furnaces, converters, slag spouts, and receiving pots, from sump, slag, slag-cars, slag heaps, and from the glowing remains removed from the furnaces, as well as from the refining pots, must be caught near their point of origin and removed. Flues and furnaces must be properly cooled and ventilated before workmen enter.

France.<sup>6</sup>—The principal regulations may be summarized as below:

1. Lead-melting pots must be placed in airy places separated from other workshops. Hoods or any other efficient means for the removal of fumes shall be installed, above the sink containing the molten lead or slag in the metallurgy of lead.

3. All work which deals with oxides and other lead compounds liable to give off dust must be carried on as far as possible in the moist state. If this is impracticable in the presence of water or other liquid, the work must be carried on mechanically in a closed and air-tight compartment.

(Where one or other of the regulations in article 1 and 3 cannot be carried out, the work in question must be done under a powerful exhaust installed in such manner that the harmful products are arrested by suitably placed appliances. Finally, if none of these methods can be adopted, the workmen must wear respirators.)

8. The introduction of food or drink into the workrooms is forbidden.

9. Employers are obliged to place at the disposal of the employees, and to gratuitously maintain, overalls and other clothing to be used exclusively in the work; also gloves and respirators.

10. In a part of the factory separated from the workshops there must be for the use of workmen exposed to dust or any other lead emanations, a well kept dressing and washing room, provided with taps and basins in sufficient number, and with an abundant supply of water as well as soap, and for each workman one towel, the latter to be renewed at least once a week.

11. A warm bath or spray shall be at the disposal of workmen exposed to dust or other lead emanations, once a week. At the close of each day's work an opportunity of taking a warm bath, or of having a warm spray, must be offered to every workman occupied in emptying or cleaning flues or dust-chambers, or repairing of furnaces, in lead smelters.

12. Employers must post, in readily accessible places, a copy of the regulations, which impose upon the workmen the following requirements: They must make use of the tools, gloves, respirators, and working overalls provided at the expense of the employer; and must not introduce into the workshop either food or drink. They must take care that before each meal their mouth, hands, and nostrils are properly cleansed, and that they take weekly or daily baths stated in No. 11.

#### CONCLUSION

From the foregoing brief outline, the need of special

precaution for the protection of those employed by lead-mining and smelting industries is apparent. The solution of the problem is simple. Workmen should invariably be informed concerning the peculiar risks they run. The lead mining and smelting industries in America should be made as safe as are the same industries in European countries.

## Clarifying Cyanide Solutions

The following notes on an experiment relating to the clarifying of cyanide solutions are given by Chester Steinem, Mogollon, New Mexico, in the *South African Mining Journal*. The disadvantages of the proposed method are obvious.

Probably the worst two zinc-box troubles are: (1) the deposition of fine ore particles on the zinc from cloudy solutions, and (2) the deposition of a zinc slime from complex zinc compounds in solution. The principal effect of the latter is to coat the zinc-shavings, making them inefficient, while the former not only has this effect, but makes much 'short zinc' and a low-grade precipitate. This low-grade precipitate necessitates more time and flux in melting. To clarify cyanide solutions, it has occurred to me that the process long used for purifying city water might be useful. This method consists essentially in adding a small quantity of potash alum in solution to the water to be purified, which coagulates the impurities in the water. The mixture is run through a settling-basin where the coagulated portion is settled out. The water is then put through a special type of sand-filter to finish the work. The process is used on river water containing the minutest clay slime and the water is so purified as to be clear and practically free from bacteria. H. W. Miller and myself made experiments to determine the effect of the alum on cyanide solution. First a sample of muddy 'box-heads' running about \$2.25 in gold and silver, was treated with alum (about 2 lb. per ton, which is a comparatively large quantity). A voluminous precipitate immediately appeared and a slight odor of HCN was noticeable. The precipitate was allowed to settle. In less than an hour all had settled except a small quantity which floated on the surface. After settling, the solution was titrated for cyanide and was found to be slightly higher than the original. The settled precipitate gave a good test for zinc. The solution was assayed for gold and silver and was found to have lost about 5c. per ton. Not having facilities for a quantitative analysis at hand, the relative amount of zinc precipitate was not determined. Considering the results, the following suggests itself for mill work: A long narrow reservoir containing baffle walls similar to those in zinc-boxes. If the final compartment is filled with oakum, excelsior, or a similar material, the sand-filter can probably be dispensed with. The other compartments should have facilities for drawing off the coagulated material at the bottom. An extra set of zinc-boxes would do for experiment. Such a scheme, while it would probably require considerable storage space, would be cheap, as alum costs but \$1.75 per 100 pounds.

ASBESTOS properties situated twenty miles southwest of Llano, Texas, are being extensively developed. The outcrop is 250 ft. wide and 1600 ft. long. It was located a few years ago by N. J. Badu, who has made an exhaustive exploration of this region. Mr. Badu recently sold the deposit to the National Asbestos Co. of Chicago, and it is this concern which is now arranging to exploit the property. It is claimed that the surface mineral shows that it belongs to the chrysolite variety of asbestos, which is in great demand for commercial purposes. The other variety known to the trade is amphibole and comes chiefly from Italy.

PANAMA has only one mine in operation, that of the Darien Gold Mining Co., but altogether 169 mines, including gold, silver, copper, iron, sulphur, asbestos, and limestone have been denounced in the republic.

<sup>6</sup>Decree of April 1908, Prescribing Special Regulations for the Hygiene of Industries in Which Workmen Are Exposed to Plumbism.

## Flotation of Minerals

By KENNETH A. MICKLE

\*The various flotation processes which are now being so largely used for separating metallic sulphides from sulphide ores depend upon differential gas and liquid attachment phenomena. The sulphides are floated on aqueous solutions as a sort of scum or froth by the agency of either gases alone or by oily substances.

In a paper by Lord Rayleigh it was shown that the presence of small amounts of various impurities in water materially affected its frothing properties. Pure water, on being vigorously agitated with air, shows very little tendency to produce a froth. This tendency is much increased by the addition of small amounts of some substances, as saponine and acetic acid. These include not only substances which are soluble in water, such as saponine and acetic acid, but substances which are insoluble in water, such as various oils and certain finely divided solid substances. Without doubt liquid cohesion and attachment effects are important factors in determining froth-producing variation, but it seems apparent that gas attachment is the chief factor, and a comparison of the various proportions of froth produced would therefore afford an approximate measurement of the attachment of air to water and to various aqueous solutions and mixtures. A series of experiments has permitted the ranging of the common materials in order according to their power in this particular.

The effect of oils in protecting minerals from being wetted by water, owing to the oiling of their surfaces, and also the affinity of oils for metals and many metallic substances has long been known. As no accurate method of measuring this effect has suggested itself, and as minerals may occur in many different forms with varying physical characters, no attempt is made here to make a definite classification on this basis. Tests were, however, carried out to show the amount of oil absorbed by minerals, and the character of the resulting product.

Mixtures of the mineral to be tested, water, and oil (with and without a small quantity of acid) in definite quantities were taken and agitated thoroughly till the character of the product became constant.

The results of these tests showed that while there are undoubtedly differences in the degree of attraction between a given sulphide and various oils, and between various sulphides and a given oil, the general behavior between various sulphides and various oils in the presence of water is practically the same in character, that is, all sulphides will become attached to all oils in preference to water. With the silicates and other rock minerals usually found in the gangue material of ores, the character of the product varies with different minerals. From an elaborate series of tests, the following was deduced.

*Adsorption of Oil in Water.*—1. Finely divided sulphides when suspended in water will adsorb varying amounts of oil. Large proportions of oil tend to form magma, and smaller proportions plastic masses and coherent aggregates. The character of these oily magmas depends upon the amount and the character of the oil used. Thick oils give viscous coherent products, and thin oils give less coherent products. Oily magmas containing considerable proportions of oil will entangle and hold gaseous bubbles with a degree of persistence which depends on the viscosity of the oil. Sulphides having an adsorption of about 5% of oil tend to attach gaseous bubbles, and this tendency increases as the proportion of oil diminishes, until a certain limit is reached, which is 0.5% or thereabouts.

2. The adsorption is more pronounced with sulphides than with such minerals as quartz, feldspar, and most of the acidic rocky minerals forming the gangue of ores.

3. Some of the silicates and other gangue forming minerals will adsorb oils in a manner approaching that of the

sulphides; for example, rhodonite, garnet, magnetite, and calcite.

4. As shown by the tests on sized minerals, the amount of oil adsorbed depends upon the extent of surface exposed.

*Adsorption in Acidulated Solutions.*—1. The sulphides will adsorb oil in the same manner to form oily magma, plastic masses, and coherent aggregations, as in the case of water and oil without acid. The amount depends on the extent of surface exposed by the minerals, as previously.

2. The gangue minerals will not adsorb oils to nearly the same extent as when no acid is present.

3. The maximum amount of oil adsorbed by sulphides in a stable manner when crushed to pass through an 80-mesh sieve (linear inch) is in the neighborhood of 10 to 15% of their weight. This is shown by the absence of excess of oil on the surface of the solution in the above tests when the percentage of oil to mineral was at or near these values. The tendency of the plastic magma to break up and form less coherent aggregates at this point also indicates this limit of true adsorption.

These determinations permit of the conclusion that when finely divided metallic sulphides are vigorously agitated with an excess of water and a small proportion of oil, the oil is adsorbed by the sulphide particles. As shown by tests on the sized material, the quantity of oil adsorbed depends upon the extent of the surface exposed. This being so, it seems safe to assume that the adsorbed oil is evenly distributed over the surface of the particles. When the quantity of oil adsorbed is very small, the general appearance of the sulphide does not differ from that of uncoiled particles. With a sulphide such as galena, which has been crushed to pass through an 80-mesh sieve, this point of apparent difference is reached when the proportion of oil adsorbed (in the case of oleic acid) is between 0.05 and 0.10%. Even with these small proportions, various physical tests indicate that the particles are oiled. This can be shown by their aversion to being wetted by water, and by the fact that the odor of decomposed oil is noticed on heating.

Such a quantity as 0.1% cannot be separated by squeezing, centrifugal force or other mechanical means, and any such quantity of adsorbed oil as 0.1% may be regarded as a true adsorption of the oil by the mineral. When more oil is added, it is probable that a secondary envelope of oil becomes attached to the primary film. When this oil is thin, there is still the attraction of the oil for the sulphide, but as the film becomes thicker the subsequent overlapping envelopes of oil are held by the attachment of one oil film for another. These overlapping films are less persistently held than the primary films, and some of the oil can be separated mechanically, as by pressure or centrifugal force. The point at which the secondary film is thickest and still stable is represented in the above tests, when no excess of oil shows on the surface of the solution.

The various stages between the primary adsorption and the putty-like product represent the gradual thickening of the secondary oil envelope. The strength of the attachment of the secondary film depends largely on the cohesion of the oil itself, the more viscous oils forming more coherent products and the thinner oils less coherent products.

In the test on sized galena crushed to pass an 80-mesh sieve but retained on a 20-mesh sieve, it was found that all the oil (5 gm. oleic acid) was adsorbed by 60 gm. of the galena. From these data, the approximate thickness of the oil film at this stage in the adsorption can be calculated. Assuming that the average size of the particles is 0.25 cm., and that the particles are cubes, the thickness of the oil film would be 0.003 centimetres.

Diagrammatic representation of oil adsorption shows the gradual thickening of the secondary film of oil from the primary adsorption to the oily magma. The oil films around the mineral particles show as concentric rings.

Oil attachments and water attachments present many similarities. A sulphide carrying 2 or 3% oil cannot be deprived of its oil by gravity, centrifugal force, or other mechanical means. Similarly in the case of wet sand carrying a like proportion of water, the water cannot be readily separated mechanically. In both cases with the

\*Abstract from a paper read before the Royal Society of Victoria and reported in the *Australian Mining Standard*.

small attachments the laws of gravity are not obeyed. With larger proportions the oil and water will separate out by gravity.

There is also a similarity between the gradual wetting of a finely crushed mineral with water, from the feebly coherent damp mineral to the thick coherent pulp, and the feebly coherent sulphide with a small proportion of oil to the various stages of oily magma. Whether the mineral particles are feebly coherent, due to the presence of a small quantity of water, or when under the surface of a solution the mineral particles are feebly coherent, due to the presence of a small quantity of oil, in both cases the interstitial spaces remain unfilled, in the first case with water and in the second with oil.

In the presence of excess of water and when the mineral has adsorbed as much oil as it will, the interstitial spaces

the attachment of the air becomes greater after a certain time has elapsed. [This is extremely improbable; doubtless dust collects upon the metal.—Ed.]

3. That the oil probably acts as an agent by which the gas bubbles are more tenaciously attached, but that it is the mineral itself which in the first place determines the gas attachment.

4. That the acid treatment tends to prevent gas attachment in the case of the gangue particles, while it does not to the same extent similarly prevent gas attachment in the case of the sulphides.

5. That attachments of carbon dioxide still cling to the particles of sulphide on settling beneath the surface of the liquid, and after the visible gas bubbles forming the scum have become disengaged. The analysis of the disengaged gas shows that it is mainly composed of nitrogen. Assuming

MINERALS' SEPARATION COMPANY'S PLANT AT THE CENTRAL MINE, SULPHIDE CORPORATION, BROKEN HILL.

become filled with the respective liquids to form coherent pulp or magma.

Mineral particles adsorb gases to an extent not generally suspected, and they also retain the gas adsorptions with such a persistence that they can neither be easily separated by mechanical means nor much affected by gravity and gas expansion. It has been shown that in the case of adsorption consisting of a mixture of gases, the respective gases may be separated fractionally, the law of gaseous diffusion apparently not being obeyed. With the view to further investigating these gas adsorption phenomena, a series of experiments were conducted that led to the following conclusions:

1. That the persistence of the attachment of the gas bubbles is increased when the surface is contaminated with some oily substance.

2. That perfectly cleaned needles and iron wire will float on the surface of distilled water under the following conditions: (a) if the water is allowed to stand for some time in contact with the air, (b) if the needles and wire are allowed to remain exposed to the air for sufficient time. In the first case, probably a layer of fine dust collects on the surface of the water, and in the second case probably

that a proportion of oxygen that would give with the nitrogen found a mixture corresponding to atmospheric air, was originally present, the fact that the gas evolved from the sulphides themselves when subjected to reduced pressure is carbon dioxide, shows that the latter is attached more persistently than is the air.

A series of measurements and analyses of gases evolved from minerals showed that from the sulphides and material containing sulphides, such as the Broken Hill tailing and slime, as a rule more gas was obtained than from the calcite and quartz. This gas consisted mainly of carbon dioxide. The residual gas, after absorbing the carbon dioxide and oxygen, was largely in excess of the proportion of nitrogen in atmospheric air, and may contain hydrogen or an excess of argon. That the carbon dioxide in these tests is not derived from the decomposition of carbonates during the experiment is shown by the negative results shown by cerussite and calcite.

These results indicate that there is apparently a concentration or condensation of gas consisting mainly of carbon dioxide on the surface of the sulphides, and to a much less extent on the other minerals tried. This gas is held persistently, and does not obey the laws of gaseous diffusion,

and may therefore be present in the liquid form. This is indicated by the fact that it is the more easily condensed gas, that is the more persistently attached. The fact that finely divided material in the form of slime will attach more gas than similar material in a coarser state indicates that the action is a surface action. It may be akin to the action of charcoal, which will absorb large volumes of the more readily condensable gases as carbon dioxide, sulphur dioxide, and ammonia. It is known that water vapor will cling most persistently to some surfaces even at high temperatures.

It had previously been found that carbon dioxide was obtained from all the sulphides tried by the aid of heat and exhaustion in the presence of water. It is probable that the gas film can only be expanded for removal in appreciable quantities in the presence of water, and that exhaustion in the dry state does not remove all the gas present. The film can be removed by solvents. The thickness of the film is probably analogous to the thickness of adsorbed oil and adsorbed water films.

When an excess of oil is attached to a sulphide it can be separated to some extent by stirring or by pressure. Similarly, if a sulphide flotation product which was floated by gas is stirred, a large proportion of the excess gas is given off. This can be seen by the larger bubbles bursting, and the shrinkage in volume of the flotation product on standing. If a flask is completely filled with some of the flotation product, and the flask is then stoppered, on standing, it will be noticed that the scum occupies a lesser volume, partly due to cooling and partly to the bursting of the bubbles and disengagement of the gases. For instance, in a large Winchester quart bottle originally completely filled with the flotation product, on standing the sulphides only occupied about two inches on the bottom of the bottle. The remainder of the space (six inches), except for five inches of solution, was occupied by the disengaged gases.

The different stages of oil and gas adsorption are analogous to a certain extent. In the test of the latter, where there is insufficient gas to buoy the mineral to the surface, but aggregates are formed (such as are brought about by weak chlorine and nitric acid solutions in the cold), there is a similarity to the aggregation stage in oil adsorptions, where a thin secondary film of oil is attached to the primary film. In the case of gaseous aggregations, flotation can be brought about by increasing the amount of attached gas; that is, by adding a saturated solution of carbon dioxide, the bubbles of the latter gas becoming attached to the aggregates, and buoy them to the surface.

Thus the stages in producing flotation of a sulphide by oil without the aid of gas are: (1) primary adsorption film; (2) secondary attachments, which will form aggregates; (3) oily magma formed by excess attachments; (4) oil sufficient to bring about the production of magma of such a specific gravity as will float in water.

Similarly, the stages gone through in bringing about the flotation of a sulphide with gas are: (1) primary adsorption film; (2) aggregates formed by secondary attachments; (3) fairly stable aggregates which float by the aid of heat or reduced pressure; (4) a scum or froth containing an excess of gas, which is mostly disengaged by agitation, after buoying the aggregates to the surface.

The results of the experiments show that (1) without the addition of acid the flotation produced by oil contains much gangue material, and (2) that the addition of acid up to a certain point decreases the amount of gangue in the flotation product.

According to *Engineering*, a London firm mainly concerned with copper-plating wood applies the name 'kuponizing' to the process it employs. In the plating of wooden hand-rails, the wooden core is first impregnated with a preservative material and then flashed with either plumbago or a metallic salt. The actual copper deposition is then carried out in a bath in the usual manner. It is the present practice to deposit a layer about  $\frac{1}{16}$  in. thick. Iron window-frames and iron pump-rams are now kuponized.

## Mining at Cripple Creek

By WILLIAM H. STORMS

Mining methods in the Cripple Creek district are not unlike those generally in use throughout the metal-mining regions of the West. The veins are stoped with the use of as little timber as possible, and many large open stopes are the result, as well as caves, which in numerous instances have extended to the surface. Some of the ground stands very well, and some of it caves readily, but it has been the practice, I may say the necessity, to hoist to the surface nearly all the rock broken underground, so that as little of the valuable mineral be lost as possible. The practice in each mine is determined by the existing conditions. The value of the ore is chiefly in gold, either metallic or occurring as some telluride of gold, generally sylvanite or calaverite, and as a rule it occurs in the softer parts of the rock, in clay seams, and on the fracture joints and cleavage planes of the rock. The miners are therefore careful to send all fine material to the surface, as well as every pound of coarse rock broken showing any indication of value, that nothing may be overlooked or wasted. As a result of these conditions, the cost of mining per ton of ore eventually recovered is high. One thing that attracted my attention was the unusual size of the ore-chutes connecting the main gangways with the stopes. These are seldom less than 3 ft. wide, and are often as much as 4 ft., and constructed of 3-in. plank. The object of this is that large masses coming to the chute may be block-holed and blasted in the chutes without serious injury to them. This is common practice in the Cripple Creek district, though I have seldom seen it elsewhere. The block-holing is done with an air-hammer drill. The greater part of the large ore masses blasted down in the stope is broken by rock hammers, or by block-holing, but large pieces are often buried beneath tons of the broken debris and these work down to the chutes as the ore is drawn off, and when exposed in a chute are broken as described.

At Cripple Creek an important factor in both the mining and the metallurgy of the ore is concentration. This commences in the mine, whenever possible, or expedient, by a rough hand-sorting of the rock broken in the vein. Upon reaching the surface the ore usually goes to a crusher and then to a washer, commonly a revolving trommel, occasionally a shaking-screen, provided with jets of water under pressure. The mines are mostly wet, and the ore comes up covered with clay and mud, so that it is often impossible to distinguish it before a clean surface is presented, and this is obtained by spraying with water in the revolving trommel, or on the shaking screen. From the washer the coarser pieces of ore pour in a continuous stream upon a belt-conveyor, along which are stationed a number of men or boys who pick out either the ore or the waste, depending upon which occurs in greater abundance; this practice varying at the different mines according to conditions. The fine material passing through the trommels is generally the richest portion; the hand-sorted rock being the next best, the coarse rock in most cases goes to the dumps. The sorted ore goes by car to bins at the nearest railroad siding, or is sent down in buckets on an aerial tramway, as at the Cresson Consolidated. The railways haul the ore either to the mills near Colorado Springs or to the smelters situated at various points.

COKE is made in Colorado, New Mexico, and Utah. Colorado's coal made into coke in 1911, according to the U. S. Geological Survey, amounted to 1,424,251 short tons, or 14% of the total output of the state. New Mexico consumed 767,108 short tons, or 25% of the total production of the state, in the manufacture of coke, and Utah 381,696 short tons, or 15% of the total output. The total quantity of coal consumed in the manufacture of coke at the mines of the Rocky Mountain states was 2,573,055 short tons, a little less than 10% of the total production.

# Mother Lode of the Klondike

By HAROLD FRENCH

In the early years of the Klondike excitement every 'sour dough' and 'cheechaco' had a guess coming as to how the gold came to get into the gravel. Some practical prospectors, pointing to the coarseness of certain nuggets, insisted that they were melted by volcanoes and blown all over the surrounding country. One eminent savant sagely stated for publication that he had discovered indisputable evidence to prove that in the glacial epoch, the valleys of the Klondike and Indian rivers were covered by a vast lake, into which rivers of ice debouched, and that mighty bergs, bearing countless tons of auriferous rock, turned turtle and deposited their precious cargoes in the bottom of the lake.

Most California miners, accustomed to the conditions of the Golden State, were positive that these rich gravels could be traced to a belt of rich quartz veins, which, as in the Sierras, they would call the Mother Lode. Fabulous fortunes are awaited the lucky prospectors who located these exiles from Sunland. When rich pay-dirt was found high on the benches of French hill and along the courses of the old channels of Bonanza, Hunker, and Dominion creeks during the winter of 1898-9, the source of the Klondike's gold was deemed near at hand. Numerous quartz locations were made on the neighboring ridges. Almost every stranded boulder was staked and re-staked by pencil and hatched prospectors. Here and there stringers of pearly white or rose-pink quartz, barren as barnacles, protruded from the prevailing country-rock, a mica schist. With sublime faith these faint indications of something better below were proclaimed to be the outcroppings of the Mother Lode of the Klondike.

During 1899 quartz prospecting was in full blast, and in that year I had the pleasure of running an assay office in Dawson for the Alaska Commercial Co. Part of my contract was to keep a lookout for a bona fide quartz mine. While most of my time was taken up in melting and assaying the company's bullion, I was permitted to do a certain amount of custom assaying of ores and to 'mush' out and inspect sundry coyote holes and prospective Comstocks and Witwatersands. Impecunious prospectors flocked to the office with samples which they 'hoped I would assay 'on a lay.' Others paid their half ounce of dust for gold and silver determinations which dashed down their hopes, for the average of hundreds of ore assays was about \$1.50 per ton. Disseminated throughout the country rock were tantalizing veinlets, or *fahlbands*, containing small amounts of gold. That the erosion and stream-transportation of vast quantities of this country rock resulted in the concentration of this gold became the generally accepted theory, but the existence of a Mother Lode seemed highly probable.

Among my clients was a mining promoter of the old school, a certain Colonel T. His credit was so good that I gladly did scores of scorifications and fusions on account. Gradually the account grew into a half partnership. I had hitched my wagon to a star. That startling developments would follow, I never doubted. He knew the West like a great stone book. He had studied the strata of almost every ridge of the Rockies, and had memorized the history of every mining camp. His genial optimism was at times most intoxicating. Certainly he and I were hiking along the high road to Bonanza and El Dorado.

One August night, the twentieth of the month, I was lounging on the porch of the company's hotel, with all the optimism of an after-dinner mood, when a trail-worn 'musher,' just in from the creeks, paused at the gate. Over his back he carried a sack that half-concealed his identity, but a familiar finger summoned me, and I awoke to the realization that this was the Colonel. Tired as he was, his face was radiant. "My boy," he greeted me, "twenty's my lucky number. To-day's the 20th, and this afternoon I've walked 20 miles. The stuff I have here is from a ledge 20

ft. wide, 20 ft. down. I want you, first of all, to start up your furnace, buck down some samples as quick as you can, put 'em through tonight, so we can get the returns as soon as possible. All I need is a few hours sleep, and in the morning I'll mush right out and locate some extensions along the strike of the ledge."

I opened the bag of samples and my eye was caught by the lustre of metallic particles disseminated through the mass. Steel-gray graphic crystals studded the quartz. Pointing to these, the Colonel shouted: "Tellurides, don't you know 'em when you see 'em? Why that's pure sylvanite, the stuff that made Cripple Creek the greatest gold camp in America. I've seen little seams like knife-blades of these here tellurides that ran one-quarter solid gold. But out on the divide between Hunker and upper Bonanza the ledge is, think of it, 20 ft. wide, and 20's my lucky number." I wasn't much over 20 myself, and I began to think that 20 was my lucky number, too. "I think I had better test this before I fire up," I ventured. "Fire up your furnace fust, and test afterwards," the Colonel commanded. I obeyed. The samples were readily pulverized on the bucking board, and in a few minutes were spread on scorifiers and placed in the muffle. Then I turned my attention to testing the powder with sulphuric acid on a porcelain plate. It gave the unmistakable pink tinge of tellurium. I told the Colonel that he was right, that he had surely struck telluride ore, and off he went, rejoicing, to sleep—perchance to dream of golden rewards.

Meanwhile, as the furnace glowed, I applied a knife to a larger particle of the steel-gray metal. It was soft, softer than copper, and under 2 in the scale of hardness. In the muffle curling clouds arose from the scorifiers, a mingling of sulphurous and tellurous vapors. The 'bullseye' winked at me and I withdrew the molten charges, poured the lead alloy into molds, and, after cooling, hammered out some rather brittle buttons and placed them on cupels and awaited further results.

Without, the busy life of this boom mining camp kept up its clamor. The ceaseless music of 'A Georgia Camp-Meeting' rang out from a neighboring dance hall in riotous reiteration. At intervals the howling of hurt *malamutes*, wailing over their wounds, bespoke the breaking up of a street fight, while, thump, thump, thump, over the board walk sounded the beats of gum-booted feet. The shadows of returning winter darkened the window at ten o'clock, so that I could with difficulty watch operations in the cherry-red muffle. Suddenly, the buttons in the cupel, one by one, seemed to brighten, and in the dim light I removed them, and to my unspeakable excitement, I found their size sufficient to account for at least \$10,000 in gold and silver in every tone of this bonanza rock.

Needless to say, I could not sleep; I could hardly wait until three in the morning, when, with stronger light I would part the buttons and compute their exact composition. Somehow, they seemed more dull at early dawn than they had appeared a few hours before. It occurred to me that possibly the cupellation was incomplete. I replenished the fuel of the furnace and, wrapping the buttons with lead foil, replaced them when the muffle had reached its proper heat. Then followed a disheartening, harrowing ordeal. At intervals I saw the smoking buttons dwindle away to half their size, to a quarter, then, as they steadily diminished, I realized the sickening truth, that in the poor light of the late evening the buttons had simply chilled. Gradually my hopes volatilized, and at five in the morning, as the cooks began to raise a racket with their pans in the company's kitchen, I saw, in each of the cupels, a tiny sparkling bead. Three of these I combined and weighed, and found that this wonderful telluride ore only contained about a dollar per ton in silver, and only the faintest trace of gold. A few tests confirmed the fact that, while this ore contained tellurides, they were only sulpho-tellurides of lead and antimony, corresponding to a compound of galena and stibnite. When the Colonel arrived and I broke the news to him, his only reply was to grab the samples and rush to a rival assayer, who told me the following evening how he had received some fairly good antimony ore, but

couldn't recommend it as commercially valuable. As my client, the discoverer of the Mother Lode of the Klondike, turned his back on me, the breakfast bell was ringing its cheerful summons to all, save me, for my appetite had gone a glimmering as had my midsummer night's dream of fortune.

## The Action of Mineral Sulphates and Arsenates on Cyanide Solutions

By ANDREW F. CROSSE

\*It has long been known that both sulphate of magnesia and sulphate of lime decompose cyanide solutions. The mineral kieserite is not rare, and has the composition  $\text{MgSO}_4 + \text{H}_2\text{O}$ , and according to 'Corney's Dictionary of Chemical Solubilities,' is but slowly dissolved in cold water. Hydrated sulphate of calcium or gypsum is also common, but it interests us more because sulphate of calcium is produced when the acidity in tailing and slime is neutralized with lime, and I have also found alumina taken up in cyanide solutions, so that probably some aluminum sulphate or double sulphate was in the ore. The first point I would like to mention is that an ordinary analysis of a mineral or sample of the ore to be treated by the cyanide process is nearly valueless.

For instance, take a common example—a certain ore contains iron, sulphur, magnesium, and other elements, according to the analysis. This analysis is no help to the cyanide manager. What he wants to know is, what will take place when the finely crushed ore comes in contact with an ordinary cyanide solution? The Mount Morgan ore near Barberton is a good example. I have seen analyses of this ore, but as far as I can remember, none of them showed any sulphate of magnesium; magnesia was mentioned and so was sulphur, and as this ore is highly pyritic, I did not think of the presence of sulphate of magnesia until I began treating the ore. I found on making a preliminary test that the ore, digested in warm water, gave a neutral reaction. In my first experiments I used an ordinary amount of caustic lime, and found the protective alkali gradually disappearing, and eventually free HCN was being given off. Then I digested some of the finely ground ore in warm water, and found magnesium sulphate in the solution. I determined the sulphuric anhydride in solution, but I found out in subsequent experiments that more  $\text{SO}_2$  was taken up when using carbonate of soda solution, or cyanide solution. I consider the best method to determine the amount of soluble sulphates present in an ore, is to take 100 gm. of finely ground ore and shake it up with 500 c.c. of warm water containing say 2 gm. of carbonate of sodium of known percentage of  $\text{Na}_2\text{CO}_3$ . I prefer to leave the mixture all night and shake it up again next morning, and then titrate the  $\text{Na}_2\text{CO}_3$  left, taking 50 c.c. of the filtered solution, and the amount of carbonate of sodium used per ton can be easily calculated. In the case of the Mount Morgan ore it was 10 lb. per ton of ore, but the same ore after treating with warm water only required 4.4 lb. of  $\text{Na}_2\text{CO}_3$  per ton of ore to precipitate the  $\text{MgCO}_3$  and  $\text{CaCO}_3$  from the aqueous solution, so that even if the ore were washed, it would still decompose a cyanide solution; therefore carbonate of sodium is necessary. This is quite an important point, for if the sulphates were easily removed by water, this would take place during crushing in the mill.

There is a peculiar vein found in the Machavie mine on the Black Reef, between Potchefstroom and Klerksdorp. The pyrite is in a globular form, and there is a large amount of graphite in this ore (the Mount Morgan ore also contains graphite). Some of the tailing from that mine after washing four times decomposed cyanide of potassium (without using protective alkali) at the rate of 0.64 lb. per ton. The unwashed sand, however, under the same treatment, decomposed 3.2 lb. of cyanide of potassium

per ton of ore. This ore contained sulphate of magnesia.

I made a long series of experiments with various proportions of CaO in solution (lime water) added to a mixture of equal parts of decinormal pure cyanide of potassium solution, and decinormal sulphate of magnesia. This seemed very nice and simple, and I thought that I should get some definite results. There was a time not so very long ago when it was imagined that all chemical reactions could be nicely expressed in equations, but unfortunately the more the mysteries of the physical world are studied the more it is found that nature does not arrange things to suit preconceived ideas. A nice equation is the following:

When equal portions of the decinormal solutions of the above salts are mixed, a precipitate of magnesium hydrate is formed, and free hydrocyanic acid is given off, but I doubt whether the reaction is as complete as the equation indicates. I thought that if I added lime-water, gradually increasing the amount till no more hydrocyanic acid was liberated (when tested by a drop of nitrate of silver solution placed on the lower side of a glass cover on a beaker) I should arrive at some definite result, but as sulphate of calcium was formed, which also dissociates cyanide of sodium or potassium, it made things complicated. Again, as more CaO solution was added, weakening the cyanide of potassium solution, hydrolysis took place. I found, however, that all the magnesium became precipitated as a hydrate. Then I also found that free hydrocyanic acid was given off, notwithstanding that, using the ordinary test, protective alkalinity as CaO was present. I am not satisfied that when a cyanide solution containing sulphates of lime and magnesia is tested by a nitrate of silver solution, that a correct result is obtained. The solutions I used were pure; but of course in practice the solutions contain zinc, which complicates matters still further. The ordinary practical man will shrug his shoulders at all this, but after all, the question is how to get over the decomposing action of sulphate of magnesium in the cheapest way. Carbonate of sodium might be found useful. No caustic soda would be formed, as carbonate of magnesium and sulphate of sodium would be produced.

Scorodite, or ferric arsenate, is not a rare mineral. It occurs often in conjunction with limonite, a hydrated ferric oxide. Probably these minerals, when found together, are the result of the oxidation of arsenical pyrite. Scorodite has the formula  $\text{FeAsO}_4 + 2\text{H}_2\text{O}$ . According to 'Corney's Dictionary of Chemical Solubilities,' it is insoluble in water, but soluble in weak hydrochloric acid.  $\text{SO}_2$  in solution also acts on it. When a finely ground mineral containing scorodite is left in contact with a weak caustic soda solution, arsenate of sodium is slowly formed. Cyanide of sodium or potassium acts in the same way, this accounts for the slow and continuous decomposition of cyanide solutions when treating ores containing arsenates. The solution becomes charged with arsenates which are reduced in the zinc-box, and the precipitated gold carries arsenic, which is not a very pleasant thing to have in the sulphuric acid treatment, as arseniuretted hydrogen, a poisonous gas, is evolved.

I have made many experiments in order to discover a method of overcoming the injurious action of arsenates on cyanide solutions, and have devised the following method: A solution of arsenate of sodium and calcium hydrate gives the following reaction:

The calcium arsenate is insoluble, and the sodium hydrate is regenerated. I ascertained by a series of experiments that, using an excess of lime and a small quantity of sodium hydrate, all the arsenate that was possible to dissolve was taken up by the sodium hydrate, then precipitated as calcium arsenate, no arsenic being left in the solution. The cyanide of sodium was unaffected by this reaction. The method I used in order to determine the amount of lime required was as follows: 200 gm. of finely powdered ore was shaken up every now and then, for seven or eight hours, with 200 c.c. of 1% NaOH solution, the amount of NaOH

\*From the *Journal of the Chem. Met. & Min. Soc. of S. A.*

used up being determined in the usual way, and for every pound of NaOH required per ton, 0.7 lb. of CaO is required in actual practice, but of course some sodium hydrate must be present in addition to act as a solvent or carrier.

For one sample of ore I treated, which contained scorodite, 13 lb. of NaOH was required per ton of ore; by this simple method I prevented the abnormal decomposition of the cyanide, and also prevented arsenic going into solution; and by regulating the proper proportion of lime, enough was left in solution to cause perfect settlement of the slime. It will be evident that ores containing soluble sulphates or arsenates may require a large amount of lime per ton in order to settle the slime; in the case of arsenates, if there is no sodium hydrate added, the sodium in the cyanide will effect solution of arsenate, and if only a small amount of lime is used, every trace of lime will be precipitated as an arsenate of calcium, and the cyanide of sodium will be decomposed. Roasted concentrate originally containing

A Light Prospecting Drill

By R. Y. HANLON

What I consider to be an excellent prospecting drill for deposits not exceeding a depth of 50 ft. is in extensive use in Australasia and the Philippine Islands. The drill, known as the 3-in. New Zealand, is a light compact hand machine, requiring six men to operate it; four upon the platform and two revolving the tubes. It consists of 3 1/4-in. flush-joint tubing in 5-ft. lengths, 1 1/4-in. squared rods fitted with 3/4-in. straight threads, platform of lumber, and clamps for arranging same upon the tubes, together with the usual complement of drill, auger, and pump. The pump is usually made 5 ft. long and fits the tubes snugly. It is equipped with a thin chilled cutting edge and a large metal check-valve ground to a close seat. This

TABLE FOR COMPUTING GOLD CONTENT OF GRAVEL, 3-IN. DRILL.

MgSO<sub>4</sub> and CaSO<sub>4</sub> still contains these salts after roasting, and an arsenical concentrate after roasting will possibly contain some ferric arsenate.

Dividends

The El Paso Con. M. Co. has declared a dividend of 1c. per share, payable June 29.

The Hedley G. M. Co. has declared a regular quarterly dividend of 3% and an extra dividend of 2%, payable June 29.

The Tonopah M. Co. has declared a regular quarterly dividend of 25c. per share and an extra dividend of 15c. per share, payable June 29.

The Hudson Bay Mining Co., Ltd. (Temiskaming mine), has declared a quarterly dividend of 3%, payable July 18. This brings the total dividends to date to 47% of the capitalization.

The United States Smelting, Refining & Mining Co. has declared a dividend of 50c. per share on common stock and 87 1/2c. per share on preferred, a total to date of \$16,098,162.

pump is very efficient in either clayey material or fine gravel, and in the Paracale district of the Philippine Islands, where this style of drill is used exclusively, I have seen five 30-ft. holes sunk in one day with only the pump employed within the tubes.

In order to pull the tubes it merely becomes necessary to loosen and drop the platform clamps, allowing them to remain loose upon the tubes, and inserting a lever and fulcrum. In this manner a 50-ft. string of tubing can be removed in an hour under ordinary conditions. The weight of each tube is a trifle less than 20 lb., and the entire weight of a 50-ft. outfit is approximately 300 lb.; easily transportable by the crew at one trip. I have attempted to use this drill in coarse gravel, but have found it unsatisfactory; principally because its lack of weight prevents it from being kept steady, and sunk vertically, any large stone deflects the tubing. But it has proved especially efficient in loam or clayey material and fine gravel or sand, also in deposits of fairly coarse and compact gravel covered with a thick subsoil or clay.

One of these drills made of 1/8-in. tubing and thoroughly equipped, costs \$175 in Manila, \$125 in Hongkong, and \$150 in Japan, so that it would perhaps be fair to strike

an average and place its price at \$150, more especially as it is hardly likely that another place can be found upon the earth which is comparable to Manila for expensiveness.

The foregoing table has been calculated upon the basis of 3-in. diameter for the tubing, this diameter checking very closely with the measured volume and with the actual extraction, and upon a gold value of 0.06c. per milligram, fineness 875 to 925. For greater depths than 30 ft. and weights over 10 milligrams, the necessary interpolation is simple and easily performed. Similar tables may be made for any other diameter of drill and fineness of gold. Where large numbers of holes are drilled such a table is a great convenience and saves much time.

## The Estimation of Ore in a Mine

By H. S. MUNROE

\*In connection with the subject of mine valuation, some charts which I use in my lectures on the subject at the School of Mines of Columbia University may be of interest. The first of these charts is intended to emphasize the importance of taking into account the specific gravity of the ore in obtaining the average value from a series of samples. For the purpose of illustration I assume five samples taken at uniform distances in a galena vein, varying in thickness from 10 to 60 in., and the ore varying from 10 to 80% of lead.

Thickness, Inches.	Lead, %	Inch- Per cent.
60	10	600
20	40	800
50	25	1250
10	80	800
10	60	600
5/150	5 215	150/4050
Averages 30 in.	43.0% (Arithmetic)	27.0% (Volumetric)

Calculating the average in the usual way by multiplying the thickness in inches by the percentage of lead and dividing by the total number of inches, an average value of 27% is found, which may be called the volumetric average. This is less than the arithmetic average, which in this case is 43%. Neither of these results, however, is correct, as the result obtained by sampling must be given weight in proportion to the tons of ore which each sample represents. In the following table I have introduced specific gravity as well as thickness.

Thickness, Inches.	Specific Gravity.	Inch- Gravity.	Lead, %	Inch- Gravity- %
60	3.0	180	10	1800
20	5.0	100	40	4000
50	4.0	200	25	5000
10	7.5	75	80	6000
10	6.0	60	60	3600
150		150/615		615/20400
	4.1 Average Spec. Grav.			33.17 Average Per cent.

If the thickness in inches is multiplied by the specific gravity of the sample, a product is obtained which may be called the inch-gravity value, which is a unit proportional to the tonnage represented by the sample. Multiplying this by the percentage of lead found by assay gives an inch-gravity-per cent product. Dividing the sum of these last products by the total of the inch-gravity column gives as the average 33.17%, which lies between the volumetric and the arithmetic average. This may be called the gravimetric average. The following example illustrates the necessity of pursuing the same plan when dealing with a gold or silver ore in which the gangue consists largely of heavy sulphides.

\*From *Bulletin* of Mining & Metallurgical Society of America.

### VOLUMETRIC (USUAL) METHOD.

Thickness Inches.	Value Per Ton.	Inch- Dollar.
15	2.00	30.00
10	1.00	10.00
5	12.00	60.00
3	20.00	60.00
2	15.00	30.00
5/35	5/50.00	35/190.00
Averages 7 in.	\$10.00 (Arithmetic)	\$5.43 (Volumetric)

### GRAVIMETRIC METHOD.

Thickness, Inches.	Specific Gravity.	Inch- Gravity.	Value Per Ton.	Inch- Gravity Value.
15	2.6	39	2.00	78.00
10	2.8	28	1.00	28.00
5	3.8	19	12.00	228.00
3	4.0	12	20.00	240.00
2	3.5	7	15.00	105.00
35		35/105		105/679.00
		3.0		\$6.47

The volumetric average obtained by the inch-dollar basis is \$5.43; the real average value based on tonnage will be \$6.47. In both cases it will be seen that the errors that result from neglecting the specific gravity of the ore may be serious. The specific gravity of the different samples may be readily determined by the bottle method, using for this purpose material from the portions of each sample which are rejected when crushing and working down the mine sample to the usual bottle sample for assaying.

I shall also call the attention of the members to the use of the well known formula for determining the probable error of the arithmetic mean of a number of observations. The use of this formula for the study of sampling data will give valuable information as to the accuracy of the final result and enable one to deal intelligently with high assays. If  $n$  = number of observations, and  $d$  = difference of each from the arithmetical mean, then the

$$\text{Probable Error} = 0.6745 \sqrt{\frac{d_1^2 + d_2^2 + \dots + d_n^2}{n(n-1)}}$$

In the *Transactions* of the Institution of Mining and Metallurgy for January 1907, E. H. Garthwaite has given some interesting results from the sampling of a gold mine in Rhodesia. In one case, the second example cited, 71 samples were taken at 2-ft. intervals. A summary of these results, as worked out by Mr. Garthwaite, is given below. It will be noticed that there are a number of high assays and, apart from this, that the range is great.

### SUMMARY OF ASSAY RESULTS.

Assay Value.	No. of Samples.	Assay Value.	No. of Samples
0-5 dwt.	13	50-75 dwt.	6
5-10 "	17	75-100 "	5
10-20 "	17	100-200 "	3
20-30 "	3	200-300 "	1
30-40 "	5	300-700 "	none
40-50 "	none	700-800 "	1
			71

Including all assays, the average value is 43.35 dwt. Applying the formula, a probable error of  $\pm 8.15$  is obtained, that is, the value lies somewhere between 35.20 dwt. and 51.50 dwt. If the one high assay, which lies between 700 and 800 dwt., is omitted, the average of the remaining 70 samples lies between 31.08 and 33.49 dwt., or, say, 32.29 dwt.; or somewhat less than the lowest probable value. Even omitting this high assay, the probable error is  $\pm 4.16$  dwt., which still leaves much uncertainty as to the real value of the ore. It is evident, in this particular case, that the ore is unusually variable, and that a safe average value can be obtained only by increasing the size of each sample or the number of samples taken. If large samples had been taken, it is possible that the variation in value would have been less and the probable error much smaller.

Mr. Garthwaite made some interesting comparisons of results that would have been obtained with other sampling distances. For example, taking every alternate sample in

the mine, he obtained two sets of results for a 4-ft. sampling interval. By taking every third sample he obtained three results, which would have been obtained by sampling at 6-ft. intervals. By taking every fourth sample, he obtained four sets for an 8-ft. sampling interval, and in a like manner, by taking every fifth sample, he obtained five different values for the mine with a sampling distance of 10 ft. These results were as follows:

Sampling Distance.	Average Value.	Average Width.	Sampling Distance.	Average Value.	Average Width.
Ft.	Dwt.	In.	Ft.	Dwt.	In.
2	43.35	32.0	8	22.74	32.0
4	35.16	32.0	10	20.26	32.5
4	50.84	32.5	10	90.37	30.0
6	28.17	32.0	10	44.85	30.0
6	66.57	29.5	10	29.97	34.0
6	33.52	33.0	10	29.87	32.0
8	35.13	31.0	Independent Sampling.		
8	79.34	32.0	10	14.60	35.3
8	33.18	33.0	10	16.00	32.0

Making the proper substitutions in the formula, we find the probable error in each case is shown in the table.

Sampling Distance.	Samples Taken.	Average Value.	Probable Error	Extreme Values.	RESULTS OBTAINED.
Ft.		Dwt.		(Theoretical)	
10	15	43.35	± 17.74	25.51 — 61.09	14.60 — 20.26 — 29.87 — 29.97 — 44.85 — 90.37
8	18	"	+ 16.42	26.93 — 59.77	22.74 — 33.18 — 35.13 — 79.34
6	24	"	+ 14.12	29.23 — 57.47	28.17 — 33.52 — 66.57
4	36	"	+ 11.45	31.90 — 54.80	35.16 — 50.84
2	71	"	+ 8.15	35.20 — 51.50	43.35 Sampling distance actually used.
1	141	?	+ 6.12	37.23 — 49.47	28.6% Probable variation.
0.5	281	?	+ 4.10	39.25 — 47.45	18.7% " "
0.25	561	?	+ 3.10	40.25 — 46.45	14.3% " "

Comparing the theoretical range, it will be seen that with the 10-ft. sampling interval the results actually obtained in the mine ranged from 14.60 to 90.37 dwt. The error of the mean is only a probable error; therefore, the actual error is certain to be more than this probable error in some cases. The same will be observed in the case of the probable and actual errors in the 8-ft. sampling interval, although the number of results being small, the variation is not so great. The 6-ft. sampling interval with only three results shows a close correspondence with the theoretical value. The 4-ft. sampling interval with only two results does not reach the theoretical extreme value. The application of the formula may be extended by computing the probable results for 1-ft., 6-in., and 3-in. sampling intervals. Under the last supposition, 561 samples would have been taken, forming a sample practically continuous, but even in this case the values would range from 40.25 to 46.45 dwt., or a range of 14.3% if referred to the 43.35 dwt. average.

## The Utilization of Atmospheric Nitrogen

The importance of nitrogenous compounds to the agricultural and industrial interests of Europe and America has prompted the Bureau of Manufactures to issue a monograph on the subject of utilizing atmospheric nitrogen in the production of such compounds. The nitrogen problem, one of the most pressing of the twentieth century: is unique from the fact that the material is unlimited. The atmospheric nitrogen above one square mile of land, amounting to about 22,000,000 tons, is equivalent to what the world would require in the next fifty years at the present rate of consumption. The problem is to utilize this nitrogen economically, and thus free the world from its dependence on the nitrate deposits of Chile, which are not particularly extensive and are likely to be exhausted at a comparatively early date.

Remarkable results have been obtained in Norway by means of electric furnaces in which atmospheric nitrogen is oxidized in the form of nitric oxide, which is used in making calcium nitrate, or Norway saltpetre. This Norwegian product is already an important rival of Chile saltpetre, but as the success of the process depends upon a very cheap supply of electricity, it will probably not be used to any great extent in the United States until

the furnaces have been made more efficient. Cyanamide, another nitrogenous fertilizer of growing importance, is being manufactured in America, and the industry should prove successful, as the production in this country of the calcium carbide required by the process is second only to that of Norway.

## Goldfield Consolidated Report

During May the total production of the Goldfield Consolidated Mines Co. was 30,215 tons, containing \$550,656.69, or an average of \$18.22 per ton; of which 29,029 tons was milled with an average extraction of 91.44%, and 1186 tons of an average value of \$28.25 per ton was shipped, the net recovery from all ore being \$16.69 per ton. The total net realization was \$309,622, or \$10.17 per ton. Of development work, 2911 ft. was performed during May. The total cost of mining, development, transportation, milling, office, and general expense was \$6.72 per ton, distributed as follows:

Mining:	
Development	\$0.82
Stoping	2.45
— \$3.27	
Transportation	\$0.08
Milling	2.20
Marketing	0.07
General expenses	0.67
Bullion tax	0.11
Marketing ore shipped	0.25
Construction	0.07
Total cost of operation.....	
\$6.72	
Miscellaneous earnings	0.12
Net cost per ton.....	
\$6.60	

The new stope in the Reilly vein, southeast of the Combination shaft produced 1100 tons of ore that averaged \$56 per ton. The 328 sill produced 50 tons of ore, averaging \$30 per ton. The downward extension of the 402-C stope, about 300 ft. north of the shaft between the fifth and sixth levels, produced 260 tons of ore which averaged \$28 per ton. This is the greatest depth at which ore has been found in this mine. The sill floor of the 3-D stope in the Sheets-Ish workings on the 150-ft. level of the Mohawk produced 200 tons of \$39 ore. The 215-X intermediate drift under the 111 stope, about 200 ft. south of the shaft, has been extended about 80 ft. through ore that has averaged \$12 per ton. This orebody is the downward extension of the big 111 stope and will produce a large tonnage of good ore. The 307-V raise, 150 ft. southeast of the shaft on the third level, passed through 10 ft. of ore that averaged \$80 per ton. This ore is the upward extension of the 307 stope that was cut off by the Mohawk fault. The 354-Q, at the south end of the 354 stope on the 450-ft. level, produced 260 tons of \$45 ore: A new section of the 407 stope on the 600-ft. level produced 648 tons which averaged \$52 per ton.

The greater part of the development in the Clermont is being done on the lower levels, where good results are being obtained, especially on the 1300-ft. level of the Grizzly Bear. From this level the third compartment of the shaft is being raised to the 1000-ft. level, and is progressing at the rate of 20 ft. per day. A drift being driven on the new orebody has been advanced about 80 ft. through ore that has averaged \$20 per ton. An average sample from the face on June 27 assayed \$76 per ton. The cross-cut has been stopped until the shaft has been enlarged and a double-drum hoist installed. After this work is completed, development on this level, as well as sinking the shaft to the 1450-ft. level, will be carried on more rapidly. In the Laguna the sump below the 720-ft. level pump station and main station have been completed, and a pump installed to raise the water in one lift to the surface. The work of prospecting the large quartz mass on this level is now in progress. The Jumbo has been connected on the 250-ft. level with the workings on the south end of the property.

## Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

### The Calumet & Hecla Mill

The Editor:

Sir—In the issue of the *Mining and Scientific Press* of June 8, a note appeared on page 809, under 'Michigan', to the effect that the Calumet & Hecla was installing Huntington mills in its new re-grinding plant. This is an error, for the machinery which has been ordered is sixty-four 8-ft. diameter Hardinge pebble-mills.

SUBSCRIBER.

Lake Linden, Michigan, June 20.

### Mutual Liability Insurance for Mine-Owners

The Editor:

Sir—A. J. Pillsbury's article in the *Mining and Scientific Press* of May 11 interests me, and I would be glad to have his opinion of a plan for mutual liability insurance confined to mine-owners of California, exclusive of coal properties. Unless the laws of this state preclude it, I would suggest that a mutual company be formed to issue policies, limiting liability to \$1000 for a single accident, or the face of policy if for less. Premiums would be such as the directors determine; perhaps the first year 5 or 10%; thereafter as statistics of losses would make necessary. A yearly dividend or return premium might accrue after the amount for a reserve or guaranty fund was set aside. This fund should be invested only in state, municipal, railroad, or other so-called 'gilt-edged' bonds. Each policyholder to be entitled to one vote, and directors and other officers to be elected by policyholders each year.

The fixed expenses need not be large; only the president, vice-president, engineers, and secretary-treasurer should be paid a salary. A small corps of inspectors would be necessary in the engineering department. The vice-president and secretary-treasurer need be the only active officers. Risks should be assumed only on properties conforming to the company's by-laws and laws of the state as to safety appliances. Of course, policies would have to be assessable, but only a *pro rata* fixed amount. I should be glad to have criticism of this plan, and also information as to whether any state laws would interfere with it.

CHARLES E. PARSONS, 2nd.

Washington, California, June 18.

The Editor:

Sir—I am not enough versed in mining to know whether there is sufficient similarity in risk and mechanism to warrant the organization of mining for the precious metals into a mutual insurance association for carrying each others' risks. I am not certain that there is a sufficient similarity between the hazards of deep quartz mining and drift mining or mining with dredges or hydraulic power to afford a sufficient community of interest to enable such miners to work together in harmony.

Again, I do not know if there is enough mining in any one of the classes of mining enterprise in the state to afford such an experience with industrial accidents as would amount to a general average risk, upon which alone a satisfactory basis of rate-making can be had. These are questions for mining engineers and mining men to determine, and not for me. They are only unanswered questions in my mind. The Legislature of California, at its recent extra session, so modified the laws relating to inter-insurance (Chapter 22) as to permit certain occupations having a similarity of risk to unite in insuring each other, but I think little use has been made of the

law so far and for the reason that employers, even those who are inter-insured as to fire risks, feel that the next Legislature will so deal with the insurance problem as probably to undo whatever might be done under this law as it now stands.

The laws of California do not now permit the formation of mutual insurance companies for covering liability or compensation risks because of industrial accident. The Industrial Accident Board is at work on the formulation of bills to submit to the next Legislature for covering the whole insurance problem, but I do not know what direction such legislation will take. There is a considerable feeling that the state should undertake insurance against industrial accident, but I am inclined to favor a rigid state control, coupled with the authorization of properly regulated mutual associations and supplemented by such a nucleus of state insurance as will make provision for the compulsory insurance of the industrial hindmost, which otherwise, through its carelessness and neglect, would be most likely to result in throwing the injured upon public or private charity. This is a rough outline of a policy that is taking shape in my own mind, but I cannot speak for others in that regard. However, I feel very certain that something definite will be done at the next session of the Legislature, and I regard it as extremely important that the mining interest, as well as others, prepare themselves for taking an intelligent and broad-minded interest in what the Legislature shall undertake to do. Meantime this Board will be very glad of suggestions from all persons who have ideas or information that will be of value to us in doing the preparatory work for legislative action.

A. J. PILLSBURY.

San Francisco, June 21.

### Mining Reports

The Editor:

Sir—In the United States it is comparatively easy for a mining manager to report to his headquarters by telegraph, and the expense of the operation is never a serious item, because the mines and company's main office are so situated that the telegraph rate, especially with the night lettergram, is reduced to a minimum. However, for those mining companies whose headquarters are in London and whose mines are situated at various points of the globe, it is necessary to condense in a telegram the maximum of information in order to save the expense of cabling at 75c. or a dollar per word. Most of the mining companies have arranged private codes, so that the development work can be reported in a way to save as many code words as possible; and as a usual thing, the telegraphic reports, which, according to a very good custom, are here published in the financial daily papers, are remarkable for their conciseness and the amount of information they contain. They not only keep the shareholder fully advised of the progress of the development work, but being published immediately on their arrival, take considerable responsibility from the shoulders of the directors. As a brilliant example of what not to do, and showing to what extremes a mine manager may be driven when he has nothing to report, the following report from the Brazilian Golden Hill mine which was published in the *Financial News* (London) is a good illustration:

"The General Manager on January 13th reports as follows:—Second level west drive shaft No. 1 driven 30 feet, total 50 feet. Stope driven west No. 1 shaft at 58 metres, driven 11 feet, total 26 feet. No. 2 adit driven 20 feet, total 315 feet. At 312 feet quartz leader was met; it is barely one inch in width and carries no value. *There is now every indication that we are close upon the first reef.*" (The italics are mine.)

With such brilliant development and under such able management, there is no doubt that this company's operations should be highly successful.

C. S. HERZIG.

London, June 11.

## Special Correspondence

### SALT LAKE CITY, UTAH

REORGANIZATION PLANS OF OHIO COPPER.—PATENTS OF MINING CLAIMS.—REPORT OF SILVER KING COALITION COMPANY.

Stockholders of the Ohio Copper Co., after a long wait, are beginning to get some direct information about the property. Unfortunately, the information is not of a reassuring trend. Back of the announcement of a plan to reorganize on a basis which will amount to an assessment of \$1 per share, it is said on authority worthy of credence, is the recent report of Henry Krumb, who was employed by bondholders and other creditors to make an examination of the Ohio. According to his report, the developed tonnage in the Ohio was sufficient only to pay the interest on the outstanding bonds for about ten years. In its anxiety to make a showing on low cost of mining, apparently the management has been cutting down the prospecting expense below the proper limit. The annual report gives the cost of mining at 26.73c. per dry ton of ore. The same report declares there are 3,200,000 tons of developed and between 9,000,000 and 10,000,000 tons of 'probable' ore in the mine. The mill has been treating about 50,000 tons per month, and the plans, if properly financed, call for a 50% increase in that capacity. During the six months from October to March, inclusive, the mill treated 311,068 tons of ore having an average copper content of 1.176%, with a total production of 3,754,866 lb. While the Ohio Copper, controlled by F. A. Heinze, is in difficulties, it is noteworthy that the Mascotte tunnel, owned entirely by Mr. Heinze, is proving a highly profitable venture through its contract with the Ohio for transportation of ores. The revenue for the six months mentioned was close to \$50,000, and it will increase in proportion with any enlargement of tonnage. The royalty is 15c. per ton. The plan of reorganization on which the stockholders will vote provides for a reduction of the par value of the stock from \$10 to \$5. The number of shares will be 1,600,000. One share of old stock plus \$1 will call for one share of the new, which has been underwritten at \$1.25 per share. This disposes of 1,260,879 shares of the new company; 250,000 will be set aside for the conversion at par of the \$1,250,000 of bonds outstanding; leaving 89,130 shares, out of which not to exceed 39,000 shares may be used as underwriters' commission. The directors state that this plan, if carried through, will pay off the floating debt, complete the mill at a cost of not over \$50,000, and leave the company approximately \$350,000 working capital.

Utah mining men are again stirred up over the attitude of the Interior Department of Washington over application for patent of mineral claims. The Department has taken the position in several cases, notably in the East Tintie case, that ore in paying quantities in place must be developed before application for patent will be granted. Geological conditions, the development of ore in adjoining properties at depth trending into the claim, neither of these may count if ore of commercial grade is not actually developed. The Commercial Club of Salt Lake City, the Salt Lake Mining Exchange, and other organizations appealed to the Utah delegation in Washington to take the matter up with a view to influencing the attitude of the Interior Department to one more encouraging to the development of mining. Assurances were received that the Department would be more liberal in the future. Now comes, however, a formal letter in defense of the Interior Department, from Samuel C. Adams, First Assistant Secretary, reiterating the former position, and giving the poor prospector little encouragement unless he has the money to open a paying mine before he applies for patent. This gives rise to the belief that only a change of administration in the Department or a change in the laws will offer hope for an altered position of the authorities.

The management of the Silver King Coalition Mines Co. has not been in the habit of giving complete, detailed information about the property, but the annual report recently issued is an exception. It shows a profit for the year ended April 30, 1912, of \$583,017.25, despite extraordinary expenditures for new equipment and purchases. An interesting feature is shown in the accumulation of a fund to pay the judgment of the Silver King Consolidated Co., in case the higher court affirms the immense verdict, and still resume the payment of dividends. The Silver King Coalition and its predecessor, the Silver King, has paid a total of \$12,334,885 in dividends. The average assay of 21,506 tons of shipping ore marketed during the year was: lead, 28.35%; silver, 50.06 oz.; gold, 0.0533 ounce.

### JOHANNESBURG, TRANSVAAL

RESULTS OF CONSOLIDATION OF RAND PROPERTIES.—REPORT OF DIRECTOR OF CROWN MINES, LTD.

A feeling has been growing on the Rand that the practice of merging the different mines into one concern has not been to the advantage of shareholders. Where large areas of worthless or lower-grade properties have been absorbed, the merger can scarcely be expected to help the shareholders when the nominal capital of the concern and costs of management have both been enormously increased at the same time. Several instances of this kind on the

SOUTH RAND SHAFT, CROWN MINES.

Rand might be mentioned, and stockholders have had to suffer, rather than those who control the management. The way out of the difficulty has not yet been discovered. Such mergers have tended to bring well meant combinations into contempt, although when consolidations are well planned and carried out, they must act to the benefit of all concerned. At the last meeting of the Crown Mines, S. Evans, the managing director, set himself the task of showing that the consolidation of the Crown, Crown Deep, Robinson Central Deep, and Langlaagte Deep had really been to the advantage of all the shareholders concerned, and in the long run the shareholders would realize that fact. He was able to point to better results in the shape of higher working profits and to some of the promises made at the time of incorporation being more than fulfilled, but he failed to convince shareholders in his explanations of why working costs had increased from 15s. 11d. in 1909 to 19s. 3d. in 1911, or that dividends of 120% in 1910 and 110% in 1911 were satisfactory when L. Reyersbaech in 1909 had forecasted 130% dividends for the stockholders as a result of the merger. The managing director, however, explained that since the merger the profitable ore reserves had been increased from 3,916,593 tons with gold content valued at over £6,000,000, to 10,124,072 tons with a total value of nearly £15,000,000 of recoverable gold content, which meant, in other words, that the profits in sight, to be realized later, had been nearly doubled since consolidation, and were estimated at over £6,000,000. When, however, the managing director came

to deal with the actual results of the combination, there were many explanations to make, more particularly with regard to the fact that at the time of consolidation the cash capital available, amounting to £721,000, had not only been spent, but another £900,000 in addition, not to mention the £300,000 spent in development, which would have to be deducted from future profits. The principal reasons for this heavy outlay were, the increasing of the capacity of the ore-reduction plant by no less than half a million tons per year more than arranged for at the time of consolidation, unforeseen expenditure in other directions, and the work having turned out to be very much more costly than was set forth in the engineers' estimates. The following striking figures were quoted as showing the results before and after consolidation:

	5 Years Before Consolidation.	Since Consolidation: 1910.	1911.
Yield per ton....	38s. 7d.	33s. 5d.	35s. 1d.
Costs per ton....	19s. 8d.	18s. 1d.	19s. 3d.
Profits per ton...	18s. 11d.	15s. 4d.	15s. 10d.

The better grade obtained in 1911 is due to closer sorting, the percentage sorted out being increased from 8.3 to 11.7%. It was calculated that at the time of consolidation 166,000 tons per month would be milled, but up to the end of 1911 this had not been attained, for in 1910 only an average of 126,000 tons per month was milled, and in 1911 134,875 tons. These disappointing results are claimed to be due to scarcity and inefficiency of labor and to troubles with the shafts at the Crown Deep and Robinson Central Deep mines. Despite all these drawbacks, the managing director claimed it only needed patience and the completion of the enlarged program to make the merger a success. The capacity of the ore-reduction plants had been increased to 212,000 tons per month, the work of seven shafts was being concentrated at two shafts whose combined output was estimated at 11,000 tons per day of ten hours, and a drift 15 ft. wide was being driven for a distance of over three miles throughout the whole length of the property, of which two-thirds had been already driven. This was to be worked by electrical haulage. Large crusher stations have been erected at the two main shafts, and it might require two or three months to get the whole of the new equipment working on a smooth-running basis. When that was achieved he felt certain that all the benefits of combination such as lower working costs, higher profits, more uniform and stable results would be achieved.

### BOSTON

ACTIVITY IN BUTTE & SUPERIOR.—UNITED STATES S. R. & M. CO. ACQUIRES COAL PROPERTY.—SPECULATION IN LONDON COPPER.

The wide swath which Butte & Superior is cutting in the market here has had the effect of broadening Boston into a general mining share market. On Wednesday, June 12, Butte & Superior reached its high mark of 51¾ in the market here and represented a larger volume of trading than any other railway, industrial, or mining enterprise on either Wall or State streets, with the single exception of Reading on the New York Stock Exchange. The following day the *News Bureau*, the official organ of State street, made this most important statement as a combination of fact and comment: "On Wednesday the Boston market became the zinc market of the country, and during the past week Boston has probably dealt in more copper stocks, zinc stocks, and coal stocks than any other exchange in the world. Boston is fast becoming the most important mining market in this country." Butte & Superior has, indeed, created a profound sensation in both Boston and Butte. People, who were hitherto entirely ignorant of zinc conditions, now take the liveliest interest in everything concerning them. American zinc has enjoyed an active market contemporaneously with Butte & Superior, and inquiry extends to various zinc situations throughout the country. New capital is going into Joplin. New mining deals of considerable mag-

nitude have been made there lately and big syndicates are securing options on additional tracts of territory. The New Jersey Zinc Co. is one of the closest corporations in the country and is reported to have paid out over 100% in dividends in a single year. Its New Jersey mine contains a remarkable body of ore running more than 20%, and a large profit is made from sulphuric acid in Wisconsin. Butte & Superior ore runs from 20 to 40%. Butte & Superior is claimed by many to be the biggest and richest zinc mine in the world, though it has not more than 3,000,000 tons of ore blocked. The breast of every drift is in ore and the bottom of the mine, at the 1600-ft. level, shows a continuation of the orebody. Engineers who have seen Butte & Superior recently, are of the opinion that it will yet turn into a copper mine at depth. The stock was first put out at Duluth, and sold as low as \$5 per share. It was reluctantly considered by Hayden, Stone & Co., bankers of Boston, until D. C. Jackling examined the property, and he recommended that \$1,000,000 of the company's convertible bonds, convertible at \$10 per share, be underwritten. Last January the stock was listed on the Exchange here and trading began around \$20 per share. It has since sold up to 51¾, and predictions are made that \$75 per share will yet be reached. W. A. Clark is largely interested in Butte zinc mining and believes that there are other coming producers of zinc in Butte, namely the Elm Orlu, which he controls; the Alice mine, belonging to Amalgamated; and the Moulton. He is rebuilding a mill for the purpose of concentrating the local zinc ores. At present he is shipping to the Washoe smelter. The treatment of Butte zinc ores is still in an experimental stage, but the Butte & Superior mill and that of Mr. Clark's will undoubtedly work out the problem. During the activity of Butte & Superior the coal issue of Hayden, Stone & Co., Island creek and Pon creek, have also been at times active. These coal and zinc movements have contributed signally to the broadening of the Boston market, suggesting that in the future it will be a general mining share market, no longer confined to copper. This is easily the most important phase of mining and market developments in Boston for the past year.

The recent activity in the shares of the United States Smelting, Refining & Mining Co. has attracted no little attention. Recently the company, which is a securities-holding corporation, issued \$10,000,000 in five-year 6% notes in order to acquire the Castle Valley Coal Co., the Black Hawk company, and the Consolidated Utah Fuel Co., in central Utah. The company has ownership and control covering approximately 100 mines in the United States, Mexico, and Alaska. It is believed that, notwithstanding the new financing necessary to acquire the coal properties in Utah, which are already self-sustaining, the company will soon increase its dividend rate of \$2 per year on the common stock. After having written off a million dollars for plant depreciation each year since organization in January 1906, the company is now earning annually about \$10 per share on the common stock. With silver at 61c. and copper at 17½c., the company's affairs are in excellent shape. Over 40% of the revenue comes from silver. The acquisition of the Utah coal properties places United States Smelting in a favorable strategic position, as it controls the bulk of the large coal deposits of Utah. The coal produced there is of excellent quality and makes good coke. With Utah coal and California oil, Boston interests figure that the Far West will get all the fuel it needs, this being in great contrast to conditions there a generation ago. The United States is largely a Boston company, though its American offices are in Salt Lake and its Mexican offices in Mexico City. James J. Storrow, formerly candidate for mayor of Boston, and a member of the banking house of Lee, Higginson & Co., is a member of the board of directors. Lee, Higginson & Co., act as the company's bankers. The common stock sold up to \$70 per share in the first year of its history and prospects are excellent for it to reach that figure again. It is now selling around 45, having advanced ten or eleven points above the low price of the year.

A few days ago a break in G. M. B. was reported from London, and the cabled advices were that the unexpected drop in price was due to the rumor of large hidden stocks of copper in the United States. This rumor was cabled to the London *Times* from New York, and it is now believed that Thomas W. Lawson, who is reported to be conducting a market manipulation in the metal on the bear side, had something to do with furnishing the information. While it is admitted that there are some speculative lines on the long account in both Europe and America, it is held here that there is no warrant for the belief that there are large invisible supplies of copper anywhere, or that there is any break coming in the demand for consumption. The loss thus sustained in London, due to the bearish rumor cabled to the *Times*, was quickly regained in the subsequent market quotations. In fact, it is reported that the leading copper interests in London took advantage of the break to buy copper at reduced figures. It is believed here that copper will be 20c. per pound before the end of the year, but the public is still slow to credit as substantial the progress being reported in the market.

### TORONTO, CANADA

#### PORCUPINE MILLS IN OPERATION.—MEETING OF THE DOME STEEL CORPORATION.

Both the Hollinger and the Vipond mills are in operation. High-grade ore will be treated at the Hollinger, the mill being constructed strictly for rich ore. The dump at No. 1 shaft contains thousands of tons of \$20 ore extracted when the property was being proved in 1910. At the Vipond the ore in the 100-ft. level in the Godfrey vein has been broken down and will be milled first, and the dump ore, averaging \$10 to \$14 per ton, will also be worked. At the Dome, all the stamps and three of the tube-mills are working steadily. Twelve raises have been put through to the surface, and drills are breaking down the ore from above. The mine will be quarried to the 100-ft. level, there being sufficient ore in sight above this level to supply the mill for some years. No development is being done at lower levels at present. Diamond-drill operations have demonstrated the continuity of the ore-body toward the Dome Extension line. It is understood that the Dome has taken an option on the La Pahue property in the Three Nations district, on which considerable work has been done with encouraging results. F. P. Schwindler has resigned his position as manager of the McIntyre, and the mine will be under the direct management of C. B. Flynn. A heavier hoist is being installed at No. 4 shaft for working the deeper levels. The Hughes is installing a compressor plant, and a large portion of the working force has been laid off until the power is available. The Dome Lake, which is installing a compressor plant, has found a wide vein in the shaft at a depth of 48 ft. The Crown Chartered has cut the fissure zone at the 200-ft. level at a distance of over 100 ft. from the shaft. On the first level over 800 ft. of underground work has been done, which revealed a number of quartz veins. Active operations have been resumed at the Pearl Lake. A station had been partly cut in No. 1 main shaft at the 300-ft. level when work closed down. This will be completed and sinking continued to the 800-ft. level. A carload of 30 tons of ore, sent by the McEneaney to McGill University at Montreal for testing, is stated to average \$18 per ton. As a further test, to decide on the character of the process to be adopted, 100 tons more will be put through the McIntyre mill. D. F. King, formerly manager of the Vane syndicate, has been appointed manager of the Achilles. The stock market continues inactive and declining, speculative buying has practically ceased. The public has completely lost faith in prospective and rose-colored anticipations of future profits, and no return of activity need be expected until practical results from the operations of the big mills are forthcoming. Hollinger, however, has shown marked strength, the stock for the last few days selling above \$13, on favorable reports sent from the mine. The Standard

mine has been closed down, as the ore-shoots, though wide, proved to be very short.

The annual meeting of the Dominion Steel Corporation was held at Montreal on June 12. The reports presented showed net earnings for the 21 months from July 1, 1910, to March 31, 1912, after payment of dividends, amounting to \$1,484,945. Of this sum \$700,000, written off as a special appropriation for depreciation and renewals, was deducted, leaving a surplus of \$784,945. A dividend of 4% was declared. The increase in output came up to expectations, but the Steel company's earnings reflected the unsatisfactory conditions of the trade in the United States as regards prices, and conditions as to counties and duties also affected this department adversely, as part of the product had to be sold in competition with duty-free imports from the American side. The coal business was satisfactory, the output for the year ended March 31 having increased from 3,862,161 tons in 1911 to 4,406,263 tons in 1912. During the year, \$1,576,931 had been expended on new collieries in Cape Breton, and \$23,353 on the Cumberland property. The new mines in the Lingan district made an excellent showing, both in the tonnage and quality of the coal, and there continues to be a good market for all coal produced. Expenditures on capital account for the Steel company amounted to \$2,714,539. The nail mill will shortly be in operation and the company will then turn its wire bars into nails, which are protected by the tariff, instead of having to sell them in competition with rods imported duty free.

### REPUBLIC, WASHINGTON

#### POWER DEVELOPMENT FOR CHEWELAH DISTRICT.—NEW CONCENTRATOR FOR THE TUNGSTEN CONSOLIDATED MINES COMPANY.

It is anticipated that the Washington Power Co. will construct a high-potential line from its plant at Long Lake the coming summer to supply for Chewelah district a long-felt need of motive power. A large sum has been spent in remodeling the mill at the Napoleon mine, near Bossberg, and placing new machinery to handle the oxidized ore. The sulphide material will be shipped to the Greenwood, British Columbia, smelter, in which the leading stockholders of the Napoleon company are interested. At the Clugston mine, east of Bossberg, an adit is being driven on a silver-lead vein, on a good grade of ore, and a considerable quantity of high-grade ore has accumulated ready for shipment. During the summer J. R. Brown, the manager, expects to push development work and make regular shipments. The lessees of the Gold Hill mine, near Myers Falls, shipped a carload of ore recently to the Tacoma smelter, which brought returns of \$48 per ton. The Granby Mining, Smelting & Power Co. of Grand Forks, British Columbia, has purchased from Jay R. Graves a 60-acre tract, bordering the Columbia river, and the island at the cataract, at the Kettle falls, and an improvement is anticipated to entail an expenditure of \$2,000,000. The deal leads people familiar with the situation to believe that the Granby company will go to Kettle falls for its power. In the Orient district a night shift has been put on at the First Thought Extension mine, to push development and work on a larger scale. A new road to the mines will be completed with the view of shipping ore to the smelter. At Loon Lake the Tungsten Consolidated Mines Co. is installing a new concentrator at the mine and expects to begin shipping concentrate in thirty days.

Chewelah district is more active than ever before in its history, and is regarded as a future producer. The United Copper Co. is now shipping a carload of high-grade ore daily and is driving a new adit with 8-hour shifts, to intersect the main vein at a depth of 1200 ft., about 3000 ft. from the portal. On the Copper Queen, owned by the same company, an adit is being driven to cut the southwest extension of the United Copper vein at a distance of about 400 ft. The company is employing 70 men. In the opposite direction, on the same vein, at

a depth of about 100 ft., Oppenheimer brothers are running on a large body of high-grade ore in the Amazon claim. R. J. Davis, who has bonded the Blue Star mine from the owners, is sinking a shaft on the vein and shipping a carload of high-grade ore monthly.

The King Solomon mine, in the Clancy district, taken over some time ago by a party of Eastern and Western capitalists in the name of a company incorporated as the Calumet & Montana, has been closed down, pending the adjustment of some difficulties which have arisen over financial matters.

## NEW YORK

POLITICAL SITUATION CAUSES INACTIVE MARKETS.—REORGANIZATION OF MINING COMPANIES.—THE COPPER SITUATION.

The centres of interest east of the Mississippi river during the past fortnight have been Chicago and Baltimore, with such financial centres as New York, Boston, and Philadelphia marking time in a rather dispirited manner. The political atmosphere is considerably overcharged, and almost anything may be expected. Market activity has come to an almost complete standstill. Such developments as have occurred have been without any great public interest. In the reorganization of Ohio Copper, which is to be made over into the Ohio Copper Mining Co., with the capital stock of the company cut in two by the reduction in par value from \$10 to \$5, the present stockholders are to have the privilege of exchanging their holdings for new stock upon the payment of \$1 per share to the old company. The Heinze interest is to be reduced, though 'F. Augustus' retains his seat at the directors' table. The new company is to be headed by W. O. Allison, president of the National Reserve Bank of New York. The new company, if all of the shareholders take care of their assessments, will start out with a cash balance of \$350,000, which will put Ohio Copper in considerably better financial shape than has been the case for some time under the Heinze regime. Some of the bondholders are much dissatisfied, as the floating debt is to be paid off at 100 cents on the dollar, while the bonds get nothing. The Old Alpha Copper Co., near Somerville, New Jersey, has once more changed hands, this time at sheriff's sale under a mortgage held by the Manhattan Trust Co. of New York. This old copper mine has been in many hands, and its career is a much-checked one. Enough money has been spent in the various attempts to produce copper from it at profit to have made a real copper mine in almost any of the copper districts of the West or Southwest. The sheriff sold the property to the new owner for the sum of \$5000. It is announced that one of the preliminary consolidations in the Cripple Creek district is completed as to details, and that the El Paso Consolidated, the Mary McKinney, and the Henry Adney are to be consolidated as a first step in the general merger that is to take in all of the important properties tapped by the Roosevelt tunnel. Some big mill plans are being prepared, and the treating of the low-grade ores will be done at the lowest possible cost. The new concern is to be called the El Paso Consolidated Gold Mining Co. The United Verde Extension is to go through another reorganization. Jerome, Arizona, seems to be destined to remain a one-mine camp. The United Verde Extension and the other properties which surround W. A. Clark's mine have been in course of development for a long time with very little progress apparent.

The copper situation remains for the most part unchanged, with a record production from many important properties. The Utah Copper in May made its highest record in the life of the property, outputting 10,068,336 lb. Nevada Consolidated production is running well above 6,000,000 lb. But notwithstanding these figures, copper authorities state that a further decrease in copper stocks may be expected in June. From which it is evident that the most important element in the copper situation at the present time is the unknown amount of copper which is held in the refineries. It is a little too much to ask the

public to believe that copper stocks can continue to shrink in the face of increased production, when in all other lines there has not been any more of a marked business revival than has yet occurred. While it is admitted upon all sides that manufacturers in Germany are—and have been for some time—going at top speed, it is also recognized that that country is very much overextended, and looking ahead as copper producers and selling agents do, a market reaction is to be expected in that quarter, rather than a continuation of the present high pressure. Last week showed a vicious drive at the copper metal market, and many stories were started to account for the break said to be about to make its appearance. Among other yarns that were revamped was the old one to the effect that the Tanganyika Concessions had a huge amount of copper about to be released from storage. This yarn is something of an old favorite in London, though it never has had any very serious consideration from those who are familiar with 'Tanks,' as the issue is known in the 'House.' The increased price in copper metal has given engineers some new and interesting problems to work out. One item is a saving in initial expense by using copper-clad steel wire in high-tension transmission. There is no development or line of industry in which the public is taking greater interest than that of hydro-electric power, and the transmission of electrical energy generally. While the idea is not welcomed by the coal roads that haul anthracite into New York, still there are to be found engineers who claim that it would be cheaper to transform the coal into power and transmit it to centres such as New York than it is to maintain a railroad to haul the coal. Experiments are said to show that a copper-clad steel wire, 0.8 in. diam., in which the amount of copper is a comparatively small item, costs no more per mile than a solid-copper wire ½ in. diam., and that more than twice as much power can be transmitted. Construction costs are much cheaper, as steel has a greater tensile strength, and supports can be placed at wider intervals. It is a rather favorable phase of the situation that, while the uses of copper multiply, the use of substitutes and methods for saving copper should also increase.

Among those unfortunates who were lost at sea in the wreck of the *Titanic* was Edgar J. Meyer, of the house of Eugene Meyer, Jr., & Co. The late Mr. Meyer was a member of the board of directors of the Braden Copper Co., and his house has always been looked upon in the Street as a connecting link between the Guggenheim interests and the house of J. P. Morgan & Co. Stephen Birch, until recently in charge of the Bonanza mines in Alaska, controlled by the Guggenheim-Morgan syndicate, has just been elected to the Braden board to fill the place left vacant by the death of Mr. Meyer. Pope Yeatman, consulting engineer for the Guggenheims, is returning this week from Chile, South America, and detailed figures as to the developed tonnage of the Braden are expected. The Guggenheims expect Braden to be one of the low-cost producers of copper, and if prophecies in this direction materialize, interests in South American copper properties should be augmented. It was recently reported that J. B. Haggin and his associates had undertaken the development of a property in Peru that was to rival or exceed in importance the Cerro de Paseo mine, controlled by Mr. Haggin, J. P. Morgan, the estate of the late D. O. Mills, and one or two associates. Inquiries at Mr. Haggin's headquarters, however, developed the fact that nothing of the kind has been undertaken. The Tennessee Copper Co., it is announced semi-officially, is to pay a quarterly dividend of \$1. With the completion of its sulphuric acid plant practically at hand, Tennessee Copper will undoubtedly remain in the dividend list for a long time to come. The British Columbia Copper Co. is operating under full swing and is earning some \$60,000 net monthly. Last month the company moved 240,000 tons of ore at one blast. This is held to be something of a record for blasting operations in mining, although larger quantities of material have undoubtedly been moved in railroad construction, by the use of giant powder.

## General Mining News

### ALASKA

#### FAIRBANKS

The mill at the Newsboy mine commenced operation in June and is treating 15 tons of ore per day. This ore comes from a 4-ft. vein which is worked from both the 115 and 215-ft. levels.

#### KENAI PENINSULA

The Kenai Dredging Co., which owns a group of claims on Kenai river near Seward, has ordered a dredge for delivery on the company's property this season. Prospecting has proved the profitable gravel on the claims to be deeper than 25 feet.

### ARIZONA

#### GILA COUNTY

(Special Correspondence.)—The Inspiration Con. Copper Co. is sinking three development shafts and one working shaft, and is opening the Inspiration orebody by drifts and raises. The development of the Live Oak orebody will begin as soon as the sinking of development shafts No. 1 and No. 2 is finished. The working shaft is being temporarily retimbered with 8-in. timbers. After it reaches the desired depth it will be lined with concrete, beginning at the bottom and working upward, removing the timbering as the concrete is poured. There will be three compartments, each 5 ft. 11 in. by 5 ft. 6 in., and the concrete walls will be 10 in. thick. It is being sunk on contract, there being three shifts with six men on each. A 25-hp. gasoline hoist is being used for sinking. About 480 men are employed. At the Miami concentrator, additional rolls are to be placed in the crushing plant so that all ore will be reduced to 1/2-in. size before going to the mill-bins. The new rolls, which are expected soon, will be 15 by 42-in. spring rolls of unusually heavy construction, specially built by the Traylor Engineering Co. All the rigid rolls now in use will be gradually replaced. The Chilean mills will be replaced by Hardinge conical pebble-mills. While the cost of steel and pebbles consumed by the latter is said to be about the same as that of steel for the former, the repair cost of the Chilean mills far exceeds that of the Hardinge mills.

F. A. Woodward, of Boston, vice-president and general manager for the Iron Cap Copper Co., is inspecting the Iron Cap mine at Copper Hill, preparatory to resuming development. The mine, which adjoins the Coper Hill mine of the Arizona Commercial, was closed in 1910 owing to exhaustion of funds of the National Mining Exploration Co. The Iron Cap Copper Co. is virtually a reorganization of that company and is capitalized for 200,000 shares, par value \$10, of which 85,000 shares are outstanding, the rest being treasury stock. There is also outstanding a \$50,000 bond issue. Mr. Woodward states that there is sufficient money in the treasury to carry on development during the coming year. A second shift has been put on at the Copper Reef mine, 12 miles south of San Carlos, and 22 men are now employed. The California adit is in 1095 ft., and has just cut what is believed may be the Daylight vein, having passed out of the limestone into a vein of porphyry and clay gouge carrying considerable calcite, red hematite, and manganese. The drift on the California vein is in 175 ft. in well mineralized matter. A fault was encountered at 165 ft., and the drift is still in this faulted zone, the amount of displacement being yet undetermined.

Globe, June 27.

#### PINAL COUNTY

(Special Correspondence.)—At the old Queen mine, operated by the Magma Copper Co. at Superior, a large shoot of high-grade copper ore has been opened on the 650 and 800-ft. levels. On the 650-ft. level it was 150 ft. long and 5 ft. wide. In the 800-ft. level it is from 5 to 20 ft. wide, and has been opened for a length of

nearly 300 ft., with neither end in sight. The ore from development is being shipped and averages from 20 to 25% copper and considerable silver. Two cars averaged over 50% copper. The copper occurs as chalcocite and bornite. The mine was taken over on the advice of Henry Krumb, about two years ago, by the Gunn-Thompson Co., which organized the Magma Copper Co. and started development. Results have exceeded expectations, and the mine bids fair to become a rich producer.

Globe, June 27.

#### SANTA CRUZ COUNTY

The R. R. R. mine, recently purchased by N. L. Amster, has commenced shipments to the Copper Queen smelter at Douglas at the rate of 40 tons per day. This ore, which is expected to run over 10% copper, is taken from a cross-cut at the 260-ft. level from an orebody 10 ft. in width. The output will be increased and by September 1 shipments of 100 tons per day are expected.

#### YAVAPAI COUNTY

The Mildred mine, near Stanton, in the southern part of the county, has found a rich body of ore in a cross-

MAP OF ARIZONA.

cut from the shaft. The vein, which is 5 ft. wide, was cut 300 ft. below a well defined outcrop. The ore is made up of galena and other sulphides, with some gold and silver. The property is equipped with a 10-stamp mill, with amalgamation plates and concentration tables. The management intends to install an aerial tramway from the shaft to the mill to carry the ore automatically through the plant with one handling. Some of the ore in the mine is rich enough to ship, but the company is planning to construct a cyanide plant if a test-run on the ore shows that an improved saving could be made by this process.

#### YUMA COUNTY

The D. & W. Mining Co. has enough ore in sight on its property to warrant the construction of a mill, according to a report made by John W. Fink, president of the company, to the stockholders. The mine, which is 18 miles northwest of Parker, has more than 3500 ft. of underground work completed and a large supply of ore opened on five levels to a depth of 700 ft. Every level is well timbered, is in good condition, and is ready for stoping. Air lines of iron pipes have been laid to supply the drills, and tracks have been laid in the levels for tramping the ore to the shaft. The mechanical equipment includes one Ingersoll-Rand, class 'J', two-stage air-com-

pressor, driven by a 42-hp. Commercial company gas engine, using distillate; one Western Gas Engine Co. 18-hp. single-drum hoisting engine, with 1000 ft. of  $\frac{5}{8}$ -in. steel cable; buckets, and cars; a Buffalo blower driven by a 5-hp. vertical gas-engine, with full equipment of pipes for ventilating the various levels; a Knowles pump and piping to lift the water from the third level of the mine to the surface. The mine was closed on June 1, but is ready to resume operation on the completion of the mill.

## CALIFORNIA

### ALPINE COUNTY

The Curtz Con. M. Co. has purchased the adjoining property of the Alpine Mining Co., which consisted of four partly developed mining claims, an aerial tramway, three-fourths of a mile in length, with a 100-ton stamp-mill, cyanide plant, dam, and power-plant on the Main Carson river. The Curtz company intends to develop more power and transmit it to Mogul, where a concentrator will be built on its property, to treat the ore now developed in its mines. There are two orebodies, one 40 and the other 60 ft. wide, which have been opened for 600 ft. in length, at depths ranging from 200 to 500 ft. This development has been carried on for four years, and over 6000 ft. of adits, shafts, and drifts completed. The ore carries copper, gold, and silver in sufficient quantity to warrant treatment by concentration.

### ELDORADO COUNTY

The Beebe mine, in the townsite of Georgetown, has discovered a body of high-grade gold ore. This property adjoins the Eureka mine and is on a continuation of the Eureka vein. Two days before the discovery of the ore it was bonded to Eastern capitalists for \$60,000. The Bright Hope mine, a mile north of Georgetown, is being operated, and the owners plan to build a mill on their property this summer.

### PLUMAS COUNTY

The Altona mine has been purchased by a syndicate headed by George H. Stephens of Seattle. The Altona was bonded several months ago and development has been in progress since then. The adit was repaired, the old tracks torn out, to be replaced by new equipment, and a station cut for a new hoist which has been placed. The sinking of a shaft on the richest of three veins in the mine, was begun, and a depth of 40 ft. has been reached. Engineers have examined the various veins and old workings of the mine for the purchasers. The mine when formerly operated was stoped to the surface, and future development must begin with sinking on the ore.

The Droege Mining Co. has given a contract to the Indian Valley Electric Light & Power Co. for electric power. This power will be available for the Droege and other mines within two months. A temporary steam plant will be installed as an auxiliary to the present hydro-electric plant at Greenville. The steam plant will develop 200 hp. It is expected, within a few months, to have power in the district from the Seneca plant to be built on the north fork of the Feather river by the Indian Valley company.

### TUOLUMNE COUNTY

The Tonopah Belmont Development Co., of Tonopah, Nevada, has purchased the Dreison mine, near Tuolumne, California.

## IDAHO

### COEUR D'ALENE

The Bunker Hill & Sullivan M. & C. Co. has completed the acquirement of patent to about 50 claims in addition to its present territory. Most of these are part of what is known as the Yreka lode, near Kellogg peak, in the Coeur d'Alene, and have been located by the corporation during the past few years. All are supposed to cover mineral ground. As a result of explorations during recent years, the geology of the Bunker Hill district has become much better established. At first the peculiar position of ore, which was found in immense lenses lying outside of the hanging wall of the vein, as well as in

the fissure proper, was supposed to indicate a zone of some width which carries all the ore. Later the underground work proved that the conditions were due to a double series of fissures, combined with faulting, which crossed each other at right angles. Acting with this knowledge, the Bunker Hill has proceeded during the past two years to acquire by purchase and location ground previously supposed to be barren, but which covered the general trend of the blind fissures discovered crossing the known system. Some of these are now in the group patented.

### NEZ PERCE COUNTY

The Gilmore Mining Co. has let a contract for work on the adit, the terms of which call for the completion of the contract within four months. This adit is started in the Gilmore ground and then cuts under some of the property of the Pittsburg-Idaho and into the Gilmore ground again, giving a depth at the greatest elevation of from 1300 to 1400 ft. By the end of this month there will be completed 800 ft. of the total 2100 ft. When the new contract work starts, it will be possible to work three faces as a drift from the 250-ft. level of the mine, which will by that time be to the adit line and thus afford an opportunity for work in that part of the ground. This adit will be used for exploration and transportation by the two properties.

The Gilmore company is shipping about one 50-ton car per week, the ore being taken out in the course of development. The returns have been showing about \$15 per ton, but Mr. Johnson says that the car now on the road probably will net \$30. This is a gold ore. The Pittsburg-Idaho is shipping about 100 tons per day, and the veins are reported as showing satisfactory orebodies with depth.

### SHOSHONE COUNTY

The Snowstorm Mining Co. is preparing to resume sinking in the winze from the No. 3 adit. A new sinking pump has been ordered, and work will be commenced as soon as it arrives. This work was started last year, and ore was found at a depth of 80 ft. It is also intended to drive a raise from the No. 4 adit level to prospect this orebody. Plans are being drawn for another unit to be added to the mill. Steady shipments of concentrate are now being made to the smelter.

## MONTANA

### SILVERBOW COUNTY

(Special Correspondence).—The experimental plant at the Washoe smelter, for the trial of the Bradley process on the concentrator slime, has been closed in order that certain mechanical changes may be made. The principal trouble has been with the dryers, which have not been able to handle the slime and get it in proper condition for the roasters. The Davis-Daly Copper Co. has filed a statement with the county assessor for the year ended May 31. The output for the year was 14,235 tons, with a gross yield per ton of \$6.80. There was an operating loss for the year of \$96,721.53, but the work of the first four months of the year involved heavy and unusual expense, which included the building of a tramway and the construction of ore-bins at the mine and at the railroad switch. In the last six months of the year the returns from ore shipments balanced the expenses. The report of the Butte-Alex Scott company shows that 25,756 tons of ore was mined in the year prior to June 1. The value of this ore was \$15.14 per ton. The total cost of mining and development was \$5.17 per ton, of transportation \$0.159, and of treatment \$3.18. The net profit for the year was \$91,581.97. The Butte Central Copper Co., which has operated the Ophir mine, has also filed its report. All the ore taken out was mined in the progress of development, and no attempt was made to do actual mining. The annual statement of the Butte & Superior Copper Co. shows a loss of \$358,013.08, as compared with net earnings for the preceding year of \$3722.26. The output was 171,796 tons of ore with a value of \$7.45 per ton. The cost of mining was \$7.89, of transportation \$1.54, and of reduction \$9.43 per ton. At present the new concen-

trator is treating from 300 to 500 tons per day, and the operating costs will undoubtedly be reduced. The Butte-Duluth has been incorporated in Butte, by local men, with a capital of \$250,000. The company is supposed to have a lease and bond on a group of claims southeast of the East Butte property. Several years ago these claims were under option to the Lewisohns, who turned them down after an examination made by J. Parke Channing.

Butte, July 1.

The report of the Tuolumne Copper Mining Co. for the year ended June 1 shows that the company mined during that period 34,324 tons of ore of an average value of \$13 per ton. Net earnings were \$24,768, a decrease of \$91,847 from the preceding year. The cost for mining was \$3.53 per ton, and for the reduction of the ore at the Washoe smelter \$4.56 per ton. The cost of labor was \$40,954, of machinery \$65,657, and of supplies \$53,572. After making a deduction for improvements, the report shows that the company operated at a loss of \$67,078 for the year.

## NEVADA

### CHURCHILL COUNTY

The Nevada Hills M. Co. has given the International S. & R. Co. a contract for the smelting of the concentrate produced in the Nevada Hills mill, and two carloads have been shipped to Tooele. This product is expected to carry about 600 oz. of silver per ton.

### CLARK COUNTY

The property of the Quartette Mining Co. has been taken over, under lease, by C. H. Jones, formerly foreman and superintendent for the company. The mine has been operated by a few lessees for some time, and Mr. Jones intends to sublet as many new blocks of ground as possible. At the mill 20 stamps have been dropping, and it is reported that enough ore is now in sight to keep the mill in operation throughout the summer. A cyanide slime plant with a capacity of 50 tons per day is working in connection with the mill.

### ESMERALDA COUNTY

(Telegraphic Correspondence.)—The production of the Goldfield Con. Mines Co. for June is estimated at 32,360 tons. The gross value of this output was \$542,000, and the operating expenses \$200,000 leaving \$342,000 as the estimated net earnings for the month.

Goldfield, July 2.

### LYON COUNTY

The Mason Valley Mines Co. has reported the output of the smelter at Yerington for the first five months of operation as follows, in pounds of copper:

January .....	709,135
February .....	1,013,601
March .....	1,285,543
April .....	1,582,164
May (estimated) .....	1,600,000
Total .....	6,190,443

This plant was started in January with one furnace, and the increased production since then is largely due to the favorable ore treated. The company is now handling 800 tons per day on an estimated capacity of 400 tons. The management has not yet determined the proper charge for depreciation of the smelter, so that no definite figure as to the cost per pound can be given. In addition to depreciation, there must also be charged to the sinking fund, as provided in the company's mortgage, 20c. per ton of ore. The matte has been shipped to the A. S. & R. Co., which has a contract for the treatment and sale of the product of the Mason Valley plant.

### NYE COUNTY

The Tonopah Merger Mining Co. has cut a promising vein in the Golden Anchor shaft at a depth of 940 ft. Since the company resumed the sinking of the shaft from the 840-ft. level it has been carried down in a well mineralized formation with small stringers of quartz. These

stringers gradually widened into an almost solid orebody, through which the shaft has been driven for 20 ft. without cutting the foot-wall of the vein, which has a general east and west course, dipping north at an angle of 35°. The importance of this discovery comes from the fact that the Golden Anchor shaft is several hundred feet outside of the proved ore-zone, being about 900 ft. west of the workings of the Midway, and about 900 ft. north of the Tonopah Extension shaft. The vein occurs in rhyolite, above the trachyte formation. Samples from the quartz stringers have given assay returns of \$50 to \$390 per ton, and the whole body of the vein would yield milling ore. Sinking will be continued to the 1050-ft. level, in the hope of cutting other orebodies. The new concentrating plant of the West End Con. M. Co. is ready to operate. This addition has been built on the north side of the mill and contains 4 Callow cones, through which will pass the product of the tube-mills, from there to be distributed to 12 Deister tables. The tailing from these tables will be pumped back to the Dorr classifier, and from there will go to the cyanide plant. It is expected that the capacity of the mill will be increased 20% by these additions, and that the plant will be able to treat a better grade of ore with a higher recovery. A reduction in the milling cost is also anticipated. It is planned to eventually increase the plant to a capacity of 150 tons per day, which can be done without installing any additional regrinding machinery. At the Tonopah Belmont property the hoisting of ore from the main shaft commenced on June 30, and the crushing plant of the new mill was started the next day. The ore-bins at the crusher plant have a capacity of 1000 tons, and the mill-bins have a capacity of 2000 tons. The latter will be filled before the mill is started.

A world's championship drilling contest, for a prize of \$1000, was one of the features of the Fourth of July at Tonopah. The second prize was \$400, together with the entrance fees of the contestants at \$10 per hammer.

## NEW MEXICO

### GRANT COUNTY

The Battleship Mining Co. has filed incorporation papers with a capitalization of \$500,000. The incorporators and directors are R. M. Henningsen, Frank Oliver, Drew Pruitt, and E. Oliver, of Los Angeles, and James T. O'Hara, of Lordsburg.

### LINCOLN COUNTY

The Cat mine, in the White Oaks district, is preparing to build a mill for the treatment of its ores. Development has been in progress for some time, a pipe-line for a water supply has been built, and a coal seam has been opened to supply the mill with fuel.

### SOCORRO COUNTY

(Special Correspondence.)—The output of the Ernestine Mining Co. for the first 10 days of June amounted to 11,300 oz. of bullion, and 5½ tons of concentrate, from a daily treatment of 100 tons. The mill of the Deadwood Mines Co., handling an average of 60 tons of ore daily, produced 4375 oz. gold and silver bullion, with about 2½ tons of concentrate during the same period. The Ernestine company has placed a new triplex electrically driven pump in the mill to handle the battery solution, replacing a steam pump formerly used. The adit at the Pacific mine of the Oaks Co. is in 510 ft., and the vein shows an 8-ft. width of good ore. The South shaft is now 187 ft. deep. Development in the last two weeks produced 80 tons of ore averaging \$21 per ton.

Mogollon, June 28.

Incorporation papers have been filed by the Mines & Metal Co. of Socorro, with capitalization of \$120,000. The incorporators are J. L. Terry, John A. McDonald, W. R. Dobson, James Redmond, and Joseph Brown, of Kelly, and H. M. Dougherty, of Socorro. The company will operate at Kelly and Magdalena, Socorro county. The directors are J. L. Terry, John A. McDonald, and H. M. Dougherty.

## UTAH

### BEAVER COUNTY

The Mines Development Co. has taken a bond and lease for four years, from April 1, 1912, on the Atlas property. The company was organized to search for a mining property which has a large tonnage of low-grade ore which could be treated by the Kidder dry-concentration process, and the officials believe that the ore of the Atlas mine can be successfully treated by this method. A deep shaft is being sunk, and there is already developed about 10,000 tons of milling ore which averages 10% lead, 8 oz. of silver, and 50c. in gold per ton. Tests have been made by J. W. Thompson, of Park City, and from the results a mill has been planned with 100 tons daily capacity. It is estimated that 85% of the lead and 80% of the silver can be saved by the Kidder process, with a ratio of concentration of four into one. This would yield 25 tons of concentrate daily, with an average value of \$37.50 per ton.

### SALT LAKE COUNTY

The Utah-Apex Mining Co. is producing from 100 to 125 tons of shipping ore and about 50 tons of concentrate per day. The high-grade ore comes from the Parvenue

MINE OF UTAH-APEX MINING CO.

adit-level, which is now 3200 ft. long and has attained a depth of about 1000 ft. The milling ore comes from the two levels above this adit, and is treated in the company's mill. The first-class ore and the concentrate are both sent to the Murray plant of the American S. & R. Co. The Parvenue adit is now being equipped for electric haulage. Two electric locomotives have been purchased, and the management expects to handle an increased output at reduced cost on account of this improvement in transportation facilities.

### SUMMIT COUNTY

The Utah Ore Sampling Co., which was organized in Salt Lake City for the purpose of taking over the Taylor & Brunton mill at Murray, the Pioneer sampling plant at Sandy, and the Silver City mill in the Tintic district, has now purchased the McIntosh ore-sampling mill at Park City. This plant, although one of the oldest in the State, is in good condition, and has a capacity of 500 tons per day.

## WASHINGTON

### FERRY COUNTY

(Special Correspondence.)—The new mill of the San Poil Con. M. Co., which is ready for operation, will give the district of Republic two modern mills for the treatment of the large reserves of low-grade ore left in the mines after shipping rich ore out of the district for smelting. The first mill, owned by the North Washington P. & R. Co., was described in the *Mining and Scientific Press* in the issue of July 8, 1911. The new mill of the San Poil company differs from the North Washington plant chiefly in the coarse-crushing department. Here a Williams pulverizer is used, treating the mine-run ore and reducing

it to 3/16-in. at one operation. This machine consists of a trommel with 32 swinging hammers on the central shaft. The trommel, which is about 9 ft. long, exclusive of driving pulleys and discharge spout, is made of 1 by 2-in. bars set 3/16 in. apart. The hammers, which revolve about 2 in. inside these bars, are rectangular pieces of special steel, about 3 by 3 by 4 in., each being attached to a collar on the central shaft with several links of chain and a pin. The central shaft with the hammers revolves at 600 r.p.m. while the trommel revolves at 100 r.p.m. in the same direction. From trial runs it is claimed that 25 hp. is required to start the crusher and 22 hp. to keep it running when once started. The output is estimated from trials at 20 tons per hour, and the full capacity of the mill, 125 tons per day, will be crushed in one shift, leaving the remaining time for repairs if necessary. The product of this crusher will be treated by rolls and then by a spitzlutte. The heavy pulp from this classifier will go to a tube-mill, and the overflow to a Dorr thickener. An Oliver filter will be used.

Republic, June 29.

The Faithful Surprise Mining Co. has developed two veins, both of which have been intersected by an adit 1268 ft. long. No. 1 vein was cut at a distance of about 400 ft. in from the portal, at a depth on the pitch of 440 ft. The ore found is free-milling gold quartz, of an average assay value of about \$8 per ton. Two other levels were opened in the same vein, higher up the hill, and some ore was shipped which assayed \$16.85 per ton. The No. 2 vein, at the end of the adit, is iron sulphide, of an average value of \$22.15 per ton, and the depth is somewhat over 500 ft. On the No. 1 vein drifts have been driven over 1000 ft. and pockets of ore were found that assayed thousands of dollars per ton.

### PIERCE COUNTY

(Special Correspondence.)—The plant of the Tacoma Smelting Co. is being overhauled and enlarged. A new copper blast-furnace is under construction, and work on another will be started as soon as the first is ready for operation. These new furnaces will be larger than those in present use, and will have 60% greater tuyere area. Only the two copper furnaces are now in operation, the lead plant is shut down and partly dismantled. One basic converter handles the output of these furnaces, and the shells of the old acid converters have been discarded. The electrolytic refinery treats about 30 tons of blister copper per day, and the rest of the product is sent to Eastern refineries.

Tacoma, June 28.

## CANADA

### BRITISH COLUMBIA

The Provincial Bureau of Mines has arranged to make assays for platinum free of charge, within the reasonable requirements of prospectors, with a view toward encouraging the search for this metal, which is known to exist in the basins of the Tulameen and Similkameen rivers. Platinum is worth \$46 per ounce at present. The assay office of the Canadian Consolidated company at Rossland was completely destroyed by fire last week, and the apparatus was a total loss. Three diamond-drills are in use at the Granby company's Hidden Creek mine, in addition to underground work. Grading for the smelter site is also in progress. Work is in progress on the Duncan property, near Beaverdell, which is under bond to the Phoenix Mining, Smelting & Development Co., and a promising showing of high-grade silver ore is being made. The mines in the Boundary district have shipped a total of 912,000 tons in 1912 to date, and the Grand Forks and Greenwood smelters have treated a total of 917,000 tons.

The British Columbia Copper Co. has a force of about 60 men employed in the development of the claims which it has under bond at Voigt's Camp on Copper mountain, about ten miles southwest of Princeton. Active work is at present being done on the 14, Ada B., Silver Dollar, Triangle Fraction, Red Eagle, and on the main working adit which is to cut a number of veins east of Voigt's

Camp. Three diamond-drills are being used at present, under the direction of W. J. Mitchell of the Northwestern Diamond Drill Contracting Co. Arrangements are being made for operating three additional machines. The ore-bodies at Voigt's Camp lie in a series of parallel veins running nearly north and south. Alternating with the veins are a series of porphyry dikes of varying widths up to several hundred feet; these porphyry dikes bear an important relation to the occurrence of the ore. There are some twenty of these veins, all of which carry copper, though all are not of working grade. The ore varies from a rather basic or neutral character on the eastern side of the series of dikes, to an acid character on the western side. The largest amount of work has been done on the 14 claim, which lies to the east of the main camp. A wagon-road has been built to this property, and two steam boilers and a hoist erected. A shaft is being sunk and is now down over 140 ft. on the incline. From the 90-ft. level a cross-cut was run through very good ore, which, in addition to copper, carried several dollars in gold. The ore consists of hematite, with calcite and chalcopryite; its peculiarity being that the hematite carries the largest part of the gold. Several drifts were run from the cross-cut, and in two of these diamond-drills are being operated at present, to determine the size and position of the orebodies. The drills are being run by steam, but a compressor is on the way, and compressed air will be available in the near future. In addition to the underground showings, several prospect shafts and a series of trenches show the size of the orebody. The ore can be reached by an adit which will have to be driven 2300 ft. This has been started of large size to accommodate two car-tracks. A diamond-drill hole has also been started at a point 25 ft. over the adit, which will be run in a line parallel to the adit, to cut all formations and not only prospect for ore, but also furnish information in regard to the rock which will be found in driving the adit.

The thirteenth general meeting of members of the Western branch of the Canadian Mining Institute convened at Greenwood, June 27, for the transaction of routine business, and the reading and discussion of several papers having particular reference to the mining industry.

#### ONTARIO

The excavation for the new 10-stamp mill of the Swastika Mining Co. has commenced. Development at the 200, 300, and 400-ft. levels has opened orebodies from which the management hopes to produce a large enough tonnage to warrant a future addition to the mill.

#### JAPAN

##### FORMOSA

A rich vein of copper ore has recently been discovered near the port of Karen on the eastern coast of Taiwan. The vein is being examined by Junkichi Kusaka of the Sendai mine inspection office.

#### MEXICO

##### SONORA

At the San Nicolas mine, south of Nacozari, a rich body of ore has been opened by two drifts on the 100-ft. level. Some of the samples taken have yielded assay returns as high as \$500 per ton in gold and silver. Shipments of the ore, which is highly silicious, have been made to the Copper Queen smelter at Douglas, Arizona. The company operating the mine has the property under bond and lease, with an option at \$75,000. A company was recently organized at Bisbee, Arizona, to be known as the Cienega Gold Mines Co., to operate properties, in the Altar district, which are reported to have gold ore in commercial quantities. The company was capitalized at \$20,000, and is a close corporation. The Nacozari Con. Copper Co. is planning to build a concentrator at its property adjoining the Pilaes property of the Moeztuma Copper Co., at Nacozari. A sufficient tonnage of milling ore has been developed to supply a small mill for an indefinite period.

## Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

E. T. DUMBLE is here.

RALPH ARNOLD has gone to New York.

EDMUND JUESSEN has gone to Arizona.

E. H. NUTTER has returned from Seattle.

H. W. TURNER has left London for Russia.

W. F. KETT is at Lake Tahoe upon his vacation.

T. H. LEGGETT was at Bowie, California, last week.

ROYAL P. JARVIS is spending the summer in Colorado.

J. MORGAN CLEMENTS was in San Francisco this week.

F. B. VAN HORN sailed from New York for Tampico, July 5.

J. W. MALCOLMSON has returned to Kansas City from Sonora.

J. B. HOEING has been appointed State Geologist for Kentucky.

E. P. MATHEWSON and family spent the Fourth at Santa Barbara, California.

G. L. CARLISLE, JR., has gone from Reno, Nevada, to Nantucket, Massachusetts.

GEORGE J. ROCKWELL is manager for the El Tajo Mining Co., San Sebastian, Mexico.

F. L. GARRISON is visiting the Comstock and will be in San Francisco about July 10.

ALFRED FOX, manager of the Caylloma mine, has returned to Peru from England.

K. MORIMURA and O. TAKAYAMA, of the Nippon Artesian Well Co., are in San Francisco.

G. A. SWANQUIST is with the Butters Divisadero Co., Divisadero, Salvador, Central America.

HENRY KRUMB is at the Keystone mine making an examination for the Inspiration Consolidated.

GEORGE I. ADAMS will be in San Francisco during the week and expects to sail for China on July 12.

J. VOLNEY LEWIS will spend the greater part of the summer visiting mining districts in the Western states.

C. L. SEVERY, having completed his engagement with the Poderosa Mining Co., Ltd., has left Collahuasi for London.

HENRY B. KAEDING is in New York and may be addressed temporarily in care of the American Institute of Mining Engineers.

F. JULIUS FOHS, after several years service as Assistant State Geologist of Kentucky, has retired to enter private consulting practice.

EDWARD L. DUFOURCQ sailed on the *Mauretania* for England and France, expecting to return to New York about the second week in August.

EZEQUIEL ORDONEZ and J. M. NICOL have been nominated as rival candidates for the presidency of the Mexican Institute of Mining & Metallurgy.

COREY C. BRAYTON has resigned as manager for the rock-crushing department of the Natomas Consolidated, and will engage in gold-dredging on the Seward peninsula, Alaska, with headquarters at Solomon.

## Obituary

CECIL BRUNSWICK SMITH died at his home in Toronto, Canada, recently. Mr. Smith, who was a graduate of McGill University, was 48 years old, was well known in the field of hydro-electric power development, having designed and built many important plants. A former president of the Canadian Society of Civil Engineers, he was the author of several texts on engineering, and his death is a great loss to the profession.

### LOCAL METAL PRICES

San Francisco July 3.

San Francisco is not a primary market for the common metals except quicksilver. The prices quoted below therefore represent sales of small lots and are not such as an ore-producer could expect to realize. Ore contracts usually call for settlements on the basis of Eastern prices, less freight and treatment charges. The prices quoted are in cents per pound, except in the case of quicksilver, which is quoted in dollars per flask of 75 pounds.

Antimony	11-114c	Quicksilver (flask)	43
Electrolytic Copper	18-184c	Tin	50-514c
Pig Lead	5.00-5.95c	Spelter	74-77c
Zinc dust, 1400 lb. casks, per 100 lb., small lots \$9.50-9.75; large \$7.50-8.50			

### METAL PRICES

(By wire from New York.)

NEW YORK, July 3.—Copper is now very quiet. Buyers are still holding off for better terms. Lead is firm and consumption is excellent. Spelter is firm and steady in price.

Average daily prices for the past week, in cents per pound, based on wholesale transactions, standard brands, are given below.

Date.	Electrolytic Copper.	Lead.	Spelter.	Silver, per oz.
June 27	17.30	4.50	7.00	614
" 28	17.30	4.50	7.00	614
" 29	17.30	4.50	7.00	614
" 30	Sunday.	No market.		
July 1	17.30	4.50	6.95	614
" 2	17.30	4.50	6.95	614
" 3	17.30	4.50	6.95	614

### SILVER

Below is given the average New York quotation, in cents per ounce, of fine silver for the months indicated:

	1911.	1912.		1911.	1912.
Jan.	53.81	56.25	July	52.57	
Feb.	52.23	59.06	Aug.	52.17	
Mch.	52.76	58.37	Sept.	52.43	
Apr.	52.32	59.20	Oct.	53.37	
May	53.31	60.88	Nov.	55.77	
June	53.04	61.34	Dec.	54.85	

### COPPER

Daily quotations on copper as published in this column represent average wholesale transactions on the New York market and refer to electrolytic copper. Lake copper commands normally from 1-5 to 1-4c. per lb. more. Below are average monthly quotations in cents per pound:

	1911.	1912.		1911.	1912.
Jan.	12.29	14.09	July	12.47	
Feb.	12.26	14.08	Aug.	12.41	
Mch.	12.14	14.68	Sept.	12.20	
Apr.	12.02	15.74	Oct.	12.19	
May	11.99	16.03	Nov.	12.61	
June	12.39	17.23	Dec.	13.55	

### COPPER SURPLUS

Figures showing the visible supply of copper at the beginning of each month are now widely available. Below are given the amounts, in pounds, known to be available at the first of each of certain months.

	U. S.	European.
January 1910	141,766,111	244,961,280
January 1911	122,030,195	230,264,280
October "	140,894,856	191,945,600
November "	134,997,642	176,816,640
December "	111,785,188	164,151,680
January 1912	89,454,695	178,329,920
February "	66,280,643	153,820,800
March "	62,939,988	141,125,680
April "	62,367,557	137,806,000
May "	65,295,368	134,176,000
June "	49,615,643	117,801,600

### UNITED STATES PRODUCTION AND CONSUMPTION

(Compiled from reports of the Copper Producers' Association)

	Production.	Domestic deliveries.	Exports.
May, 1911	126,962,544	64,543,963	61,078,557
June	124,554,312	61,655,561	71,460,519
July	112,167,934	56,982,582	74,880,658
August	125,493,667	59,935,364	69,885,660
September	115,588,950	57,311,584	50,824,011
October	118,255,442	64,068,656	60,084,349
November	111,876,601	68,039,776	67,049,279
December	122,896,697	65,988,474	79,238,716
Total for 1911	1,431,938,338	709,611,945	754,932,733
January 1912	119,337,753	62,343,901	60,167,904
February	116,035,809	56,228,368	63,148,096
March	125,694,601	67,847,556	58,779,566
April	125,694,001	69,513,846	53,252,326
May	126,737,836	72,702,237	69,485,945

**LEAD**

Lead is quoted ordinarily in cents per pound or dollars per hundred pounds delivered at St. Louis or New York. The difference is normally 15c. per hundred pounds, and any larger or smaller difference is promptly met by sales. The daily price in New York is published each week in this column. Below are the average quotations by months:

	1911.	1912.		1911.	1912.
Jan. ....	4.48	4.43	July .....	4.50	....
Feb. ....	4.44	4.03	Aug. ....	4.50	....
Mch. ....	4.39	4.07	Sept. ....	4.48	....
Apr. ....	4.41	4.20	Oct. ....	4.27	....
May ....	4.37	4.20	Nov. ....	4.30	....
June ....	4.34	4.40	Dec. ....	4.45	....

**ZINC**

Zinc is quoted as spelter, standard Western brands, and based upon St. Louis or New York delivery. While New York quotations, as a matter of convenience, are commonly used, relatively little spelter actually goes to or comes from New York. The bulk is shipped direct from the plants in the Mississippi Valley to manufacturers, due allowance being made for freight. New York daily quotations are published in this column each week. Below are given averages by months:

	1911.	1912.		1911.	1912.
Jan. ....	5.45	6.42	July .....	5.70	....
Feb. ....	5.52	6.50	Aug. ....	5.95	....
Mch. ....	5.56	6.57	Sept. ....	5.86	....
Apr. ....	5.40	6.63	Oct. ....	6.10	....
May ....	5.35	6.68	Nov. ....	6.38	....
June ....	5.50	6.84	Dec. ....	6.30	....

Zinc-dust is quoted separately, the price being based upon the cost of spelter in Illinois and the cost of preparation. About half the zinc-dust used in the United States is imported through San Francisco. Delivery prices are determined largely by quantities and contracts.

**QUICKSILVER**

The primary market for quicksilver is San Francisco, California, being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average monthly quotations, in dollars, per flask of 75 lb., are given below:

	1911.	1912.		1911.	1912.
Jan. ....	44.60	43.75	July .....	48.00	....
Feb. ....	48.40	46.00	Aug. ....	50.00	....
Mch. ....	52.50	46.00	Sept. ....	47.50	....
Apr. ....	50.90	42.25	Oct. ....	46.12	....
May ....	46.50	41.75	Nov. ....	45.50	....
June ....	46.50	41.30	Dec. ....	44.50	....

**TIN**

New York prices control in the American market for tin, since the metal is almost entirely imported. San Francisco quotations, averaging about 5c. per lb. higher than New York, are quoted weekly in this column. Below are given average monthly New York quotations in cents per pound:

	1911.	1912.		1911.	1912.
Jan. ....	41.25	42.53	July .....	42.40	....
Feb. ....	41.61	42.96	Aug. ....	43.32	....
Mch. ....	40.16	42.58	Sept. ....	39.75	....
Apr. ....	42.18	43.92	Oct. ....	41.18	....
May ....	43.11	46.05	Nov. ....	43.12	....
June ....	44.61	45.40	Dec. ....	44.65	....

**Current Prices For Chemicals**

(Corrected monthly by Braun-Knecht-Helmann Co.)

Prices quoted are for ordinary quantities in packages as specified. For round lots lower prices may be expected, while in smaller quantities advanced prices are ordinarily charged. Prices named are subject to fluctuation. Other conditions govern Mexican and foreign business.

	Min.	Max.

## Company Reports

### SILVER KING COALITION MINES COMPANY

This company was formed in 1902 to acquire 327 patented mining claims, covering 2158 acres, in the Park City district, Utah. Thomas Kearns is general manager. During the year ended April 30, 1912, 107,893 tons of ore was mined, of which 86,387 was concentrated, producing 14,106 tons of concentrate, a ratio of concentration of 6.12 into 1. Details of production follow:

Product.	Dry Tons.	Lead, lb.	Silver, oz.	Gold, oz.
Crude ore	21,506	12,194,390	1,076,711	1185
Concentrate	14,106	9,661,137	715,367	1174
Totals	35,612	21,855,527	1,792,078	2359

Sold for \$1,269,827.03.

Average assay value per ton:

	Lead, %.	Silver, oz.	Gold, oz.
Crude ore	28.35	50.06	0.0551
Concentrate	34.24	50.71	0.0833

The total receipts amounted to \$1,277,638, and the expenditure to \$694,410, leaving an operating profit of \$583,018. The assets of the company are valued at \$6,768,250, and the company is capitalized at \$6,250,000. During the year the company, jointly with the Daly-Judge and Daly West Mining Co. purchased 700 acres of land and constructed an impounding dam for mill tailing. The entire flow of Silver creek is conducted through a concrete flume to the dam, and the outflow is thoroughly settled before being allowed to escape. This will free these companies from the litigation which has harassed them in the past. The judgment which the Silver King Consolidated Mining Co. obtained against the Coalition company has been appealed. Several of the larger stockholders have given individual bonds covering the judgment, and meanwhile the earnings of the company are being set aside for the protection of the bondsmen. Development during the past year has explored the Uintah Treasure Hill and has connected the stopes on the Crescent vein with the apex. This latter work has proved the apex, discovered new ore-bodies, and provided additional ventilation and means of exit. The mill, sampler, and tramway are now operated by electric power, and operating costs have been materially reduced because of this, the improved ventilation, and the use of hammer-drills in stoping.

### BRAKPAN MINES, LIMITED

This company was formed in 1903 to acquire mining rights from the Transvaal Coal Trust Co., Ltd., of which it is a subsidiary. The authorized capital is £750,000, in shares of £1 each, all being issued. Details of operation for the year, as given in the report by W. L. Honnold, the consulting engineer, are as follows:

At the end of the year 241,204 tons had been milled, the average recovery being 27s. 6.58d. per ton as against an average working cost of 18s. 4.16d. These figures were influenced by a number of abnormal circumstances incidental to starting, chief among which were: (1) the initial absorption of gold by the plates, tube-mills, and cyanide works, estimated, owing to the influence of the Merrill and Butters processes, at only about 2400 oz.; (2) partial extraction of the gold contained in about 11,000 tons of sand and slime representing the current stock of the cyanide plant; (3) higher cyanide residues than now obtain; (4) the inclusion of 31,300 tons of accumulated dump ore, the first 16,500 tons of which came from the preliminary opening of stopes and were therefore presumably of about average grade, the remainder coming from the development dump and averaging probably not over half the value of stope ore; (5) an underestimate of tonnage during the first months of milling, due to certain factors not then having been definitely determined; this was partly offset by imperfect sorting in August.

The net significance of the abnormal circumstances justifies the conclusion that, had operations been on the basis since established, and had the ore from current development been normal as to quantity and value, the recovery would have been at least 6d. per ton higher than shown. The working cost of 18s. 3d. per ton reached in December is open to further reduction. To what extent, is a matter of considerable uncertainty. Development for the year totaled 10,675 ft., averaging for the 9701 ft. on ore 10.07 dwt. over 32.89 in. The ore reserve was re-estimated in the light of milling experience, and is returned at a somewhat lower tonnage but higher value, namely, 1,925,346 mine tons at 6.73 dwt., as against 2,035,108 tons at 6.62 dwt. at the beginning of milling. The altered position, apart from the influence of milling and new development, is mainly due to the elimination of certain previously included low-grade narrow areas which, in view of work since done, as well as because of the limitations of machine mining, now looks less promising. Detailed sampling of the stope faces as they have been advanced points to the gold in some sections of the mine being so distributed as to permit of selective mining to a greater extent than was at first thought practicable.

With regard to the underground position, it seems probable that the system followed in laying out the mine will provide the advantages anticipated. In the matter of development it has so far resulted in the opening of an area measuring at extreme points 2800 ft. along the strike by 6600 ft. in the direction of the dip, this area being centrally situated and affording an uncommon degree of evidence as to the nature and future of the property. From this area development can now be simultaneously extended in four directions, and at as many points as circumstances may call for. It should be borne in mind, however, that with levels placed so far apart as is permissible in the case of a flat-lying mine such as Brakpan, more time is required to render a certain developed tonnage effective as to stoping than in a mine having closely spaced levels. Perhaps equal effectiveness in this respect will never be realized. Furthermore, it is probable that with the ore reserve developed in such large blocks it would be difficult, until a surplus of stopes were available, to maintain the regularity of output heretofore aimed at on the Rand.

These restrictions, however, quite apart from their more or less transitory bearing, seem relatively unimportant in view of the fact that, for a given expenditure on development, a much more comprehensive and, on the whole, more stable position is secured, as well as certain advantages from the standpoint of working. In the matter of breaking and handling ore it has been necessary, in face of the somewhat unusual conditions which prevail, to adopt certain methods not commonly in practice here. The application of these called for and still calls for a guarded but to some extent experimental attitude. Much progress has been made, however, and it now seems that the initial difficulties will prove of even less importance than anticipated. A point of notable significance is that, owing mainly to the comparatively large reef width and favorable dip conditions, it has been found practicable to utilize machine-drills to a much greater extent than expected, thus relieving an otherwise serious labor shortage.

The equipment promises to fully meet expectations. More time will be required, however, before a definite statement will be possible as to the advantages of its various features, particularly those involving a departure from previous practice.

Capital expenditure has exceeded expectations to about £50,000, say 4½% of the amount involved. This is due partly to the fact that at the earlier date construction was at a stage which precluded exact analysis, partly to the delay in starting milling, and partly to certain unforeseen requirements, more particularly the additional compressed air and machine-drill equipment called for in consequence of the recognition that only by adopting machine mining to an almost exclusive extent could the best results be secured from the labor available.

## Book Reviews

Any of the books noticed in this column are for sale by, or can be procured from, the MINING AND SCIENTIFIC PRESS.

**HOW TO LIVE IN TROPICAL AFRICA.** By J. Murray, M.D. Second edition. Pp. 315. Ill. *The African World*, London, 1912. For sale by the *Mining and Scientific Press*. Price \$1.40.

This volume, published by *The African World*, will be of great service and convenience to engineers who may be called upon to visit tropical countries for longer or shorter periods. Much has been written concerning sanitation and hygiene in tropical countries, but the material is widely scattered, and the engineer who is called upon to 'brush up' on these problems will be grateful to Dr. Murray for so concise and comprehensive a summary. The book is not a mere manual of direction, but briefly and lucidly discusses underlying principles, and will be correspondingly serviceable to engineers in other countries than Africa. Much of the information is, indeed, of general service, and the book will be a useful addition to any engineer's library.

**PRINCIPLES OF INSURANCE.** By W. F. Gephardt. Pp. 313. The Macmillan Company, New York, 1911. For sale by the *Mining and Scientific Press*. Price \$1.60.

Social development is gradually making insurance a prime factor of modern life. The growth of insurance companies, spread of fraternal and benefit associations, and, more recently, the expansion of liability insurance, have made it desirable that the ordinary citizen should be possessed of an elementary knowledge of the fundamentals of insurance. But even the policy-holders of insurance companies usually are devoid of any clear conceptions of the principles of insurance, nor are agents usually able to inform them, as their attention is devoted to securing applicants rather than enlightening them. Mr. Gephardt, who is an assistant professor in Ohio State University and a former insurance salesman, writes lucidly for students and general readers, who will be grateful to him for his clear exposition of the theory of life insurance; mortality tables; the selection of lives; the company; the premium; policies; reserve, surplus, and dividends; investments and interests; the relation of the state to insurance; insurance for the wage-earner; and accident and health insurance. The volume concludes with a brief bibliography of insurance which will be useful to those who may wish to push their study of the matter further. The chapter on insurance for the wage-earner contains an excellent discussion on employers' liability, both in America and abroad, and of pension systems, which will be of much service to all employers of labor. The book is marred by crudities of expression, such as the use of 'expressively' for expressly, and the obsolete form 'invalidity' for invalidism, but is readable, nevertheless, and is likely to be widely appreciated.

**ANNUAL TABLES OF CONSTANTS AND NUMERICAL CHEMICAL, PHYSICAL, AND TECHNOLOGICAL.** By the International Committee of the Seventh Congress of Applied Chemistry. Pp. 727. No index. The University of Chicago Press, Chicago, 1912. For sale by the *Mining and Scientific Press*. Price \$6.54 postpaid.

This ponderous volume, replete with data, is the fruit of the efforts of the committee appointed by the Seventh Congress of Applied Chemistry at London in 1909. It has been prepared under the patronage of the International Association of Academics, by a group of over thirty of the best known physical and applied chemists of Germany, France, and England, and is published simultaneously in Paris, Leipzig, London, and Chicago. The volume issues under the date of 1910, but, on account of the necessary labor of preparation, the appearance of the volume has

been much delayed. For this reason the index has been omitted, the omission having been partly supplied by the usual French analytical table of contents, which the American reader commonly does not find to be of much service. The amount of care taken in preparing the tables may be inferred from the fact that postcards are enclosed with each volume so that readers may report at once any error that may be detected. The introduction and chapter headings are given in French, German, English, and Italian, but the tables are in French, the language most likely to be easily intelligible to the other nationalities, though the tables might have been improved by departing from Continental usage, such, for example, as the use of the comma for the decimal point. The tables are unusually complete, covering all the most important physical and chemical constants of the elements and their compounds and alloys. The volume is bulky, and it might be wise in succeeding issues to divide it into several parts. An illumination engineer would be grateful for the tables on radiation and reflecting power, but would care nothing about colloids and vapor pressures. Considering its size, the book is very cheap; a valuable feature, since it is scarcely worth while to prepare tables and publish them in so expensive a form that few will feel able to afford them. The volume will be a welcome one to chemists and physicists, and is likely to quickly create a place for itself.

**DESIGN OF MILL STRUCTURES.** By Milo S. Ketchum. Pp. 459. Ill, index. McGraw-Hill Book Co., New York, 1912. For sale by the *Mining and Scientific Press*. Price \$4.

This is a new book in a field never previously covered in any satisfactory manner. The author is a professor in the University of Colorado, and an experienced writer as well as engineer. While the book is supplementary to his 'Design of Steel Mill Buildings' and 'Design of Walls, Bins, and Grain Elevators,' it is self-contained, and is comprehensive.

The general description of the various 'Hoisting Arrangements and Methods,' up to page 21, with examples from actual existing works, is clearly and ably given and covers the subject in a very instructive manner. The subject of 'Hoisting Ropes,' to page 28, details of 'Cages and Skips,' to page 40, are also fully described, and clearly shown in the illustrations. The 'Stresses of Head-frames and Structures,' from page 41 to page 91, are explained and demonstrated thoroughly. The subject is treated in every detail, and is such as will enable the designing engineer to follow the formulæ in making standard calculations. The descriptions of the various head-frames, to page 147, are clear and explicit. The illustrations are complete and amply cover the many types used in good practice. 'Coal Tipples,' to page 197, also are clearly illustrated and described, and the ones chosen form a good typical collection.

The chapter on design of roof trusses, to page 240, while being a reprint from some of Mr. Ketchum's other works, is valuable and makes the chapter on 'Graphics and Calculations' clear and complete in itself. The design of bins and retaining walls, to page 278, is concise, interesting, and complete, explaining the necessary calculations fully. The discussion of 'Coal Washers,' to page 290, is good, fully described, and contains typical illustrations, as is also true of 'Coal Breakers,' to page 305. 'Miscellaneous Structures,' to page 316, covers construction used in mine structures.

Many of the tables in the chapter on 'Design, Costs, and Tables,' to page 371, are new and useful, and the part on 'Specifications' covers the subject fully and is excellent reference in making specifications for any detailed requirement. The various subjects described and illustrated are all based on good practical working plants, and make them particularly valuable reference. The compilation is the best that I have seen; in fact, I do not know of any other book that supplies such information, and treats the subject of mine structures—especially of head-frames—in one volume. The author should be highly commended for producing so useful a book.

LIGNITE IN THE FORT BERTHOLD INDIAN RESERVATION, NORTH DAKOTA, NORTH OF MISSOURI RIVER. By Max A. Pishel. Advance chapter from Bulletin 471, 'Contributions to Economic Geology, 1910, Part II.' U. S. Geol. Surv. Bull. 471-C. 19 pp.; maps, plates. Washington, 1912.

## Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

**TUBE-MILLS** were first used for the fine grinding of ore in 1894 at the Moulton mill, at Butte, according to R. F. Abbé.

**SHOOK** is a term applied to the staves and head of a barrel when knocked down and bound together for shipment. Material for boxes, when packed the same way, is also termed shooks.

**LITHIUM** salts give to the non-luminous flame a carmine red color, which is visible as violet through a blue glass, but is obscured by a green glass, giving a distinction from potassium.  $\text{LiCl}$  is soluble in absolute or amyl alcohol, while sodium and potassium chlorides are almost insoluble.

**QUICKSILVER** lost in milling at the Ready Bullion mill of the Alaska United amounted to 35.5% of the total used. Practically all this was lost in the mill, the loss during retorting being less than 2% of the total. The loss per ton milled was approximately 1/15 oz., or a little over 1 oz. quicksilver per ounce of free gold recovered.

**GRAPHITE** imported into the United States nearly all comes from the island of Ceylon, and the United States has for many years been the principal market for this Ceylon product. Considerable amounts of graphite are also imported into the United States from Mexico, and within the last few years graphite from Korea has entered the market.

**AMBLYGONITE** was extensively mined in 1907 and 1908 at the Peerless mine, near Keystone, North Dakota, by Herman Reinhold, of the Western Chemical Reduction Co. of Omaha, Nebraska. The mass of amblygonite was about 20 ft. wide, was pearly white, and had one good cleavage plane. It has been worked to only a slight depth, but has produced several hundred tons of ore.

**JOINTS** in air-transmission lines must be carefully made so as to prevent leaks and to eliminate friction as far as possible; allowance must be made for expansion and contraction, especially if the pipe is carried above ground; pockets in the line without means of emptying the segregated moisture must be avoided, and finally, provision must be made for repairs to the pipe-line should these be necessary.

**HOLMES** method of riffle tables and launders employs a wide steel tray placed directly under the screen, sloping in the same direction, and fitted either with or without riffles. This steel tray, which catches the screenings, empties on to another trap sloping in the opposite direction, which in turn delivers the material on to a set of divided sluices fitted with riffles and sloping toward the stern.

**STEPS** by which the miner develops or constructs his title or ownership to a lode or placer claim, are by initiating a possessory right by making a discovery, completing it by acts of location and record, maintaining it from year to year by annual labor; and perfecting it to the fee-simple or absolute title after placing \$500 worth of improvements upon it, by obtaining patent for it from the General Land Office at Washington, through entry and purchase at the local land office.

**TAILING** and dumps which have been abandoned are subject to re-location if upon unoccupied public land, but if the land is in private ownership such material be-

longs to the owner of the surface rights and is not open to location. Tailing from a mill which is in operation, if it escapes upon the land of other persons or upon public land, ceases to be the property of the mill-owner. Where the land belongs to another, he may claim damages and later exact a royalty for the privilege of re-working the tailing. If the tailing escapes upon public land it is open to location as a placer deposit.

**BELTS** should not be replaced on pulleys while they are running at high speed if long service is desired. Belts should not be used too tight, nor should the lace-holes be punched too close together, or too near the end. Two large a punch should not be used. It is cheaper to break the lacing than tear the belt, and there is no great objection to allowing the lacing to fold in the holes. Belting should not be allowed to run against the splice, and animal or mineral oil should not be used in dressing rubber belting; boiled linseed oil is best. Idlers should not be used unless absolutely necessary, as a belt running free lasts longer. A long belt should be heavier than the horse-power indicates, otherwise it will whip. A heavy belt requires a larger pulley to give the best service.

**NITRATES**, solid and in solution, may be detected by the use of a reagent made by treating 5 gm. zinc amalgam with a mixture of 5 c.c.  $\text{HCl}$  (1.18) and 5 c.c. of 1% solution of strychnia sulphate. Boil, cool, and decant. Of the reagent, 0.5 c.c. is added to 10 c.c. of the water to be tested. Nitrites, if present, give a red coloration at once and can be colorimetrically estimated. If 5 c.c. of  $\text{H}_2\text{SO}_4$  is added, a coloration due to nitrates appears, which can be estimated in the same manner. If it is desired to estimate nitrates direct, add to 10 c.c. of the water 2 drops of  $\text{NH}_4\text{OH}$ , and 3 or 4 drops of acetic, and evaporate to dryness to eliminate nitrites. A repetition of this treatment may be desirable to effect complete removal. Finally, take up with 10 c.c. of water and test for nitrites as above.

**ALLOYS** of steel have been extensively investigated by railroads and rolling-mill operators, in order to produce a rail that will give more satisfactory service than the ordinary rail now in use. One of the principal metals used in these experiments, according to the U. S. Geological Survey, is titanium. More than 250,000 long tons of rails were rolled in 1910 from steel to which ferro-titanium had been added. More than 150,000 tons of steel rails in which nickel or nickel and chromium were used as alloy were also made during 1910, and experiments were made with about 80,000 tons of steel rails in which chromium, manganese, vanadium, and other metals were used. Certain steelmakers are now advertising titanium steel, claiming that although no titanium is left in the steel, the removal of gases and impurities effected by it greatly increases the good quality of the steel.

**CHROMIUM** is mainly used in pigments and in connection with special tanning processes. It is also used in furnace linings, to a small extent in steel alloys, and in the manufacture of other alloys, among which is one known as 'chromax bronze.' Though the domestic production of chromic iron ore in 1911 was small, the importations were large, amounting to 37,540 tons, valued at \$407,958. In addition chromic acid and bichromate of potash were imported to the value of \$3508. Chromic iron ore is widely distributed through areas of serpentine and associated basic rocks in different parts of the United States. Such areas have been found in a few localities in the old metamorphic rocks east of the Appalachian region from New England to Georgia; at various points in the Rocky Mountain region; throughout the extent of the Sierra Nevada and Coast Ranges in California, and at a few points in the Cascade mountains. It is widely disseminated through many of these areas, but only locally is it concentrated into workable deposits.

## Catalogues Received

ALLIS-CHALMERS Co., Milwaukee, Wisconsin. Bulletin No. 1626, 'Hydraulic Turbines.' 8 pages. Illustrated. 8 by 10 inches.

SENN-SMITH CONCENTRATOR Co., Hearst Bdg., San Francisco. Bulletin No. 1, 'Pan Motion Concentrator.' 6 pages. Illustrated. 8½ by 6 inches.

THE LUNKENHEIMER Co., Cincinnati, Ohio. '1912 Catalogue and Price List of Engineering Specialties.' 654 pages. Illustrated. 5¼ by 7¼ inches.

CARNEGIE STEEL Co., Pittsburg, Pennsylvania. Pamphlet 'Structural Beams.' Information and data on new line of I-beam sections. 12 pages. Illustrated. 5 by 8 inches.

THE HAYWARD Co., 50 Church street, New York. Pamphlet No. 588, 'Hayward Buckets and Digging Machinery.' 8 pages. Illustrated. 6 by 9 inches.

LINK-BELT COMPANY, Chicago. Book No. 121, 'Ewart Friction Clutch.' 18 pages. Illustrated. 6 by 9 inches. Also booklet, 'Link-Belt Locomotive Cranes.' 32 pages. Illustrated. 9 by 6 inches.

THE BRISTOL Co., Waterbury, Connecticut. Catalogue No. 1000, 'Bristol Recording Gauges for Pressure and Vacuum.' 64 pages. Illustrated. 10½ by 8 inches. Also, Bulletin No. 132, 'Bristol's Recording Ammeters,' 48 pages. Bulletin No. 144, 'Bristol's Round Form Recording Pressure Gauges,' model 52, 4 pages. Bulletin No. 148, 'Bristol's Round Form Recording Pressure Gauges,' models 50 and 56, 8 pages. Bulletin No. 166, 'Bristol's Patent Automobile Time Recorder,' 4 pages. All illustrated. 10½ by 8 inches.

MERRILL METALLURGICAL Co., 143 Second St., San Francisco. Covering the Merrill Zinc Dust Precipitation Process, the Merrill Automatic Sluicing Pressure Slime Filter, and the Merrill Sluicing Clarifying Filter. Illustrated. 7½ by 11 inches. This series of catalogs is an excellent example of the high-class technical material that is now included in manufacturers' catalogs. Together the pamphlets constitute practically a manual on zinc-dust precipitation and filter-press treatment of sand and slime. Detailed figures of operating costs are given with exact data as to quantities and time. Included in the pamphlets are reprints of several excellent technical articles. The material is attractively printed, well illustrated, and the text is sound as well as excellently presented. No engineer interested in cyanidation can afford not to have a copy.

A most artistic and complete catalogue of mechanical rubber goods has recently been issued by THE DIAMOND RUBBER Co., Akron, Ohio. It consists of 160 pages. Each page is a tint-block with a halftone of the article described at the top and the product in actual service shown at the bottom. Reading matter is attractively arranged around and between the halftones. The color combination is brown and red on a black tint. It is divided into sections on 'Transmission Belt,' 'Conveyor Belt,' 'Hose,' 'Packings,' 'Moulded Goods,' 'Mats and Matting,' and 'Hard Rubber.' Also, an additional section is devoted to Diamond tires and other Diamond products. Valuable information covering data on belting, hose, packing, etc., is scattered plentifully throughout the entire book. A clever scheme is carried out in the end-sheets, which are a series of the Diamond trade-marks with the characteristic word 'Diamond' diagonally across the double-page spread. The cover is artistic. The design illustrates the wide range of industries that use Diamond products.

## Commercial Paragraphs

J. D. HULL, Seattle, Washington, has recently accepted the agency of the Edgar Allen American Manganese Steel Co. His territory is to be the western half of the state of Washington.

ALLAN W. MARKS, formerly with De La Vergne Refrigerating Co., is now associated with H. W. Johns-Manville

Co. as refrigerating engineer, with headquarters at the San Francisco office. Mr. Marks has had extensive experience in installing refrigerating plants for marine and other service.

## Switch-Boards for Small Mining Plants

The equipment necessary for the control and distribution of electrical energy for small mining plants is simple, comparatively inexpensive, and in general, similar to that used in street railway systems using direct-current generators for power. Since one side of the system is grounded, the switching, protecting, and measuring apparatus is reduced to a minimum, it being necessary to take care of the generator and feeder circuits of a single polarity only. However, to obtain safe and satisfactory service, there are a few features which, if not absolutely essential, are at least advisable. The equipment should be of sturdy construction and good workmanship, and the panel supports should be insulated from ground to lessen the chance of short circuits. The circuit-breakers in the generator circuits should be connected between the negative brushes and the series field to protect the machines from grounds,

either internal or between the machine and the panel. The switching equipment should be such that when machines are run in multiple, the series field of the incoming machine may be connected in multiple with those of the running machines and the voltage adjusted before closing the main switches, as this arrangement insures the correct polarity of the incoming machine and the least disturbance in paralleling.

Often, too, in small mining plants, a separate source of power is not always available for operating the station and switchboard lamps. This may be taken care of by a lighting switch and fuses on each generator panel, using lamps of the same voltage as the generators or of lower voltage and connecting them in series. The lighting circuits should be connected between the circuit-breaker and the machine and not to the bus-bar, so that the station can be lighted from any machine before the power is thrown on the line, and also to prevent the station from being thrown in darkness should the breakers on all machines open. These points have been taken care of in a new line of 250/275 and 550/575-v. small mining plant switch-boards lately turned out by the General Electric Co. These switch-boards can be ordered direct from descriptive Bulletin No. 4877, containing illustrations, specifications, wiring diagrams, and all other necessary information.

# THE PARRAL TANK SYSTEM OF SLIME AGITATION

(PATENTED)

*The Most Efficient and Economical System. Operates the Continuous Process in Flat Bottom Tanks of any Height and any Diameter. In Successful Operation in PARRAL, ZACATECAS and GUANAJUATO. Superior Results Guaranteed.*

# THE WEDGE MECHANICAL FURNACE

## PATENTED

---

### CAST-IRON SHAFTS ELIMINATED BY MODERN PATENTED DESIGN

Years ago when we first began building furnaces for private use, we used cast-iron shafts, with the arms bolted to the shaft. We tried various designs, and our experience was probably similar to what yours has been if you have used *large* furnaces having cast-iron shafts.

It is necessary to cool a cast-iron shaft, which was done in our early designs, with air, and later with water. This type, having the arms bolted to shaft, necessitates shutting down the furnace to replace an arm. These interruptions are expensive. Further, as everyone knows, cast-iron about a furnace, exposed to the heat and gases, is sooner or later eaten out. Further, the replacing of a cast iron shaft or sections of same, is an undesirable expenditure of money and labor.

To do away with all these difficulties, the same type of construction was adopted in the shaft as is used in the walls of the furnace. The shaft is protected by the brick, the same as the outer shell is protected by brick walls.

Further, an arm can be changed in a hot furnace in less than an hour's time. This all means economy in operation.

Write us, stating analysis of ore, concentrates, mixture or material you desire to roast, characteristics and physical condition of same, number of tons to be treated per twenty-four hours, and results you desire in the calcine.

# Yuba Gold Dredges

## Yuba Suction Dredges

## Yuba Centrifugal Pumps

Gold Dredge equipped with 15 cu. ft. buckets operating at Natoma, Cal. Designed and Built by The Yuba Construction Co. for the Natomas Consolidated of California.

Gold Dredges built with steel or wood hulls and equipped with buckets of 1½ cubic feet to 15 cubic feet capacity each. Always designed to meet the conditions under which they are to operate.

WE DESIGN AND BUILD:

### Small Gold Dredges

With steel or wood hulls designed and built for properties where transportation is difficult.

### Centrifugal Pumps

Especially adapted for irrigation, mining and hydraulic dredging.

**SUCTION, DIPPER AND ELEVATOR DREDGES**  
and other excavating machinery.

**GENERAL MACHINE SHOP WORK, CARBON, MANGANESE AND OTHER  
ALLOY-STEEL CASTINGS**

# World Beaters!!

The following list of "Moveable" or Type A, Moore Filter Process Plants, treating in the aggregate several thousands of tons of Gold and Silver slimed ores DAILY in the Pachuca District, Mexico, have as the result of their high efficiency, put a q-u-i-e-t-u-s on the making of further installations of the "Stationary" or Type B, in that region.

Negociacion Minera de San Rafael y Anexas.  
Compania Beneficiadora de Metales "La Union, S. A."  
Compania Minera de Natividad y Anexas, S. A.  
Compania Purisima Grande, Guadalupe y Anexas.  
Compania de Minas La Blanca y Anexas, S. A.  
Negociacion Minera de Santa Gertrudis y Guadalupe, S. A.  
Compania Beneficiadora de Metales, Haciendas de San Francisco,  
Pachuca, S. A.  
Senor Gabriel Mancera.  
Rincon y Anexas, S. A.  
Compania Beneficiadora de Pozos, S. A.  
Compania Minera El Barreno y Anexas.

Our Engineering Staff, which is at your service, is of a very high order—as it should be, when the question recovering the last "trace" of Gold and Silver values once reduced or put into solution, is involved.

Coupling the Clancy Electrochemical Process with the Moore, the combination for high extraction, minimized loss of Cyanide, complete "displacement" (recovery) is perfect.

We are guaranteeing one of the companies in Mexico having at present an installation of the "Stationary" Filter (not of our designing, however) an economy of \$100,000 per annum, by adopting our Moore-Clancy Process, which will include changing over to the "Moveable" Type of working the Process; so you see, we are still quite in the "running."

# This Record of Tunnel Driving Will Interest You

STEWART MINING CO.

Kellogg, Idaho, Nov. 24, 1911

TO WHOM IT MAY CONCERN:

This is to certify that the Stewart Mining Company have driven a 6 x 7 foot tunnel (in the clear) 117 feet in seven days, working three 8-hour shifts with the following crew per shift: one machine man, one car man and two muckers, running the dirt 1300 feet.

This drilling was done with a C-110 "Butterfly" Rock Drill.

(Signed) WM. A. BEAUDRY, Supt.

# Consider their Simplicity— Butters Filters

The **ONLY** slime filter that operates by **CAPILLARY ADHESION** of cake. There is no drying—no cracking and no loss of cake in transfer. There can be no uneven percolation.

Butters Filters are **SIMPLE**—no lifting and carrying of the leaves

that can cause vibration—no risk of accidents.

Slime assaying only **55 CENTS PER TON** is profitably treated by the Butters. **EVERYTHING** is gotten out with a Butters—there's **NO WASTE**.

# In Ore Dressing

the classifying of the particles by means of screens or hydraulic classifiers to facilitate the elimination of the gange by concentration, is a necessary preparation.

Screening, or classification by size, is sufficient for the simple separation accomplished by jigging. However, concentration of fine material on tables and vanners is more complex and screen classification is found unsatisfactory. Hydraulic classification under free settling conditions is recognized as being more efficient in preparing ore for concentration on tables and vanners.

The development of a hydraulic classifier, operating perfectly, has been the aim of millmen for many years. This result, however, was not achieved until the value of the hindered settling principle was recognized and adopted by Professor Richards in his Hindered Settling Classifier. (This classifier produces a feed best prepared for concentration on tables and vanners.)

***We build two types of classifiers involving this principle which we can fully recommend***

**The Richards Hindered Settling Classifier**—the automatic type—is successful in the smallest as well as the largest plants.

**The Richards-Janney Classifier**—the mechanically operated type—is particularly adapted to large tonnage.

# DODGE

## Split Wood Pulleys

July, 1882

July, 1912

Thirty Years

In Service

**W**HEN you buy wood split pulleys, you should be sure to get good pulleys; pulleys that will prove to be an investment, not an expense.

Dodge "Independence" are good wood split pulleys. Just as good as selected, seasoned, kiln-dried stock, combined with skilled workmanship and twenty-eight years of "knowing how" can make them.

The proof of any pulley is in the running. Dodge wood split pulleys are balanced, and run true. They are backed by the Dodge guaranty. There are over three million "Independence" wood split pulleys in successful operation and the output each year is greater than the year before.

There are reasons for this. First, the quality and merit of the pulley. The facility with which it can be mounted on the shaft. The interchangeable bushings, by means of which it fits all sizes of shafting within a wide range. The perfect shaft fastening without keys or setscrews. The superior belt surface. And, last, the moderate price as compared with pulleys of any other type.

Dodge wood split pulleys will run satisfactorily anywhere that regular leather belting can be used.

# Testing for Metallurgical Processes

By JAMES A. BARR

216 Pages—Illustrated—Indexed—\$2 Postpaid

**T**HIS BOOK is designed to assist in the selection of the process of treatment for any ore. The author describes the apparatus employed in making laboratory and small-lot tests. It is founded upon experimental work at the Michigan College of Mines, and the methods recommended have been tested in practice. It is brief and practical, equally valuable to the student and the practicing engineer.

PUBLISHED AND FOR SALE BY

MINING AND SCIENTIFIC PRESS, 420 MARKET STREET, SAN FRANCISCO

THE MINING MAGAZINE, 819, Salisbury House, LONDON, E. C.

Furnished with or  
without back gear

## Designed for the Miner

The new G-E induction motor specially designed for mining service has the following important features:

- |  |   |
|--|---|
| High starting effort.                          | End rings have large ventilating surface.                   |
| Large capacity for severe overloads.           | All parts interchangeable.                                  |
| Can be temporarily stalled without injury.     | Moisture proof insulation.                                  |
| Unusually strong mechanical construction.      | Windings in open slots.                                     |
| Totally enclosed except for air ducts.         | Extra large bearing surface of rotor spider keeps it tight. |
| Ample ventilation given by fan on motor shaft. | End shields can be removed without disturbing back shaft.   |

Your inquiry when received is assigned to an expert on the application of electricity to mining, who thereafter handles all your correspondence with the result that your needs are studied—understood—and delays are avoided.

# THE BRAUN PLANETARY PULVERIZER

Will successfully pulverize hard—soft or talcy rock to any degree of fineness up to 200 mesh. Capacity to 80 mesh: 1 lb. in 40 seconds, 90 lbs. in 1 hour.

Simple to operate.

No expensive parts to be replaced.

The planetary movement is warranted to last indefinitely.

PATENT APPLIED FOR

More easily cleaned than a buckboard.

Grinding Discs are renewable.

Almost noiseless in operation.

But to assure all these advantages you must get the **Braun Planetary Pulverizer**—a product of the experience of the oldest and largest exclusive makers of Labor Saving Laboratory Appliances.

# Traylor <sup>Heavy Duty</sup> Crushing Rolls

**are fitted with features which allow you to produce a uniform product with larger capacity at a lower cost than any other form of crusher.**

- ¶ They are fitted with an automatic side adjusting mechanism which operates the stationary shaft side ways  $\frac{1}{2}$ " in every 120 revolutions, thereby presenting a new face continually to the movable roll which eliminates corrugating or channeling of the roll shells, and allows you to wear the shells down to less than  $\frac{1}{2}$ " thick without putting a tool of any kind on the roll surface.

- ¶ They are designed extra heavy, with large diameter of shafts, so that you are able to crush the hardest kind of ore, rock or quartz for the least cost of up-keep.
- ¶ The many repeat orders we are receiving for these rolls demonstrates beyond the question of a doubt the superiority of these machines.

*Send for Catalog G-2, describing in detail the construction of Traylor Rolls.*

**We also build a full line of Stamp Mill, Concentrating, Cyaniding, and Smelting Machinery**

# INDUSTRIAL LOCOMOTIVES

FOR BURNING COAL, WOOD OR OIL

The construction of our standard light locomotives embodies all the essential features which experience has taught us go to make up a satisfactory locomotive.

They are the product of wide experience, are built for hard work, simple in design, have a minimum number of moving parts and are accessible for making repairs. The wear and repair of a locomotive are in direct proportion to the number of movable parts.

Every piece of material which enters into their construction must first undergo a severe test and must conform to rigid specifications. This insures the use of proper materials for every part.

In buying a locomotive from us you get the benefit of the knowledge of engineers who make a study of locomotive requirements, the experience gained in building over 50,000 locomotives, and the guarantee of a \$50,000,000 company.

# L. D. G. Heavy Duty Compressors

Cross Compound Two Stage Corliss Compressor Installed at Philadelphia, New York, Mare Island, Paget Sound and Pearl Harbor, P. I., Navy Yards.

¶ L. D. G. *Heavy Duty* Compressors are built with three paramount objects in view:

¶ FIRST:—*Perfection of Design*, resulting in the compression of air with the lowest possible power cost.

¶ SECOND:—*Reliability* and *Low Maintenance Cost*, secured by combining the most perfect designs with the best workmanship and materials possible to obtain.

¶ THIRD:—*Accessibility* to all working parts and *Freedom from Complicated Mechanism*.

¶ These features represent *True Compressor Value*. As the total operating cost will equal the first cost in from *two to five years*, the purchase of a compressor because of its low first cost is very poor economy.

*Our Corliss Air Compressors are described in Bulletin L 523-32*

# The Leading Mills Endorse Dorr Classifiers and Thickeners

Endorse them by the most convincing of all endorsements—by using them in their own work.

¶ For instance: The Santa Gertrudis is using 26 Dorr Machines. The Tonopah-Belmont are installing eight Classifiers and eight Thickeners. The Real Del Monte have, in all, 31 Dorr Machines in their numerous mills.

¶ In fact, Dorr Machinery is a part of the equipment of practically every up-to-date plant.

¶ Would it not pay you to investigate and see *why*? Write us—we will gladly go into details.

## "EMPIRE" GOLD DREDGES

Show the largest returns on the investment represented, because, while saving all the values, they require the minimum operating and up-keep expense, leaving larger profits than any other dredge can show. This is "Empire" service.

## "EMPIRE" PROSPECTING DRILLS

Have never failed, under any conditions, to do more work in less time and at less cost, with greater accuracy, than any other prospecting drill.

**New York Engineering Company**  
2 Rector St., NEW YORK

Star Drilling Machines are rapid drillers, and they do not consume all the profits for renewals and repairs.

There are fewer wearing parts than in any other drill. A strong steady pull and a quick positive drop are imparted to the drill rope.

The gear wheel on the bull wheel shaft for rapid pulling and running in of tools, the slanting Sampson post, the solid band wheel, the running board, and many other minor improvements, are details that you should know about.

# WE SPECIALIZE IN PLACER DREDGE MINING EQUIPMENT

## Some of Our Work in 1911

We designed and installed a dredge with special equipment for mining **Placer Tin** in Alaska.

We dismantled a 7½ cu. ft. dredge, hauled the machinery 33 miles through the mountains of California, sawed out lumber on the ground, and had the rebuilt dredge in operation in 6½ months.

We built a 3 cu. ft. gold dredge near Nome, Alaska, in 31 days.

## This Season we are building 5 Gold Dredges for Alaska

We are prepared to undertake the dismantling and rebuilding of dredges in any district.

3 Cu. Ft. Gold Dredge Driven by Distillate Engines,  
Operating near Nome, Alaska.

# GOODRICH

## Conveyor Belts

**Lowest cost  
per ton of  
material handled**

Buying a belt by its first cost is like looking through the wrong end of a telescope—the cost merely looks small.

The whole matter of buying conveyor belt should sift down to this one bedrock question: "How much will it cost me *per ton* of material handled?"

The belt that will handle the most material and carry it longer is the belt that costs you the least in the long run; and you are buying belts for "long runs."

You cannot, of course, know from personal experience that GOODRICH CONVEYOR BELTS cost less per ton of material handled—but you can be guided by the record of this belt in the hands of others in your line.

For full particulars address—

**The B. F. GOODRICH COMPANY**

**Akron, Ohio**

**LARGEST IN THE WORLD**

# TWO BIG FACTS

## The Reinforced Center—The Cushion Edge

# Diamond Patent Conveyor Belt

### Reinforced Center

Note the arrow pointing to the extra cover. This added center is where all the load is carried and abrasion and wear the greatest.

It more than doubles the wearing thickness of the belt.

The Reinforced Center can be made to cover the entire top surface if desired.

### Cushion Edge

Note the arrow pointing to the Cushion Edge. It takes all the wear due to side rails and idlers, and the fabric is never reached.

When the edges of an ordinary belt wear slightly the fabric is exposed, moisture is admitted, the plies separate and the belt speedily ruined.

1,200,000 tons of material were conveyed by one of these belts in the gold fields of South Africa.

¶ More than 50% of all conveyor belts used in South Africa are Diamond Belts.

¶ We compete with the world's best belt builders in securing this business—and on an efficiency basis the Diamond Belt always wins.

¶ In the United States Diamond Belts are conveying annually billions of tons of material—slashing records by their wonderful feats of endurance.

¶ We have facts and figures to lay before you which knock mere claims into a cocked hat. The only thing of interest to you is the reduction of your conveying costs. We have tangible proof of exactly what we can do.

¶ Centralize your responsibility—put it up to us to cut your cost—our combination of knowing how to build a belt and having belt experts to assist you in selecting the right belt for the right place is the best guarantee in the world for getting most for your money.

¶ Then Write Us To-day for a sample of this Belt—get in touch with Diamond goods and Diamond service.

## THE DIAMOND RUBBER CO.

AKRON, O.

DISTRIBUTING STATIONS IN ALL PRINCIPAL CITIES

# THE RUGGLES AERIAL CARRIER

## WILL DO EVERYTHING BUT TALK

This cut shows the Ruggles Aerial Carrier being used in the excavating of a canal. The material is being picked up and deposited on the sides. Later when the canal was completed and the water turned in, the same equipment was used to pick up the rock and load it into barges for transportation to a crushing plant.

THE use of this device reduces your aerial transportation system to the most simple form and allows the lowest possible cost of operation. With it there is no endless traction rope, and a single drum engine is ample for power purposes.

The Ruggles Aerial Carrier will lift a skip, or other load, from any distance to the cable, automatically unlock itself, move in either direction on the incline, automatically lock and either dump the skip in the air or lower a load to the ground. All these operations are controlled by the hoisting engineer through a single line from the hoisting drum and with no signal except that to start. The return trip is equally simple and automatic.

The brake on the carrier is independent and does not hold by gripping the cable, thereby reducing the wear on the latter to an absolute minimum.

# The Extensive Use of Westinghouse Motors For Mine Pump Service Proves Their Great Reliability

Only a thoroughly reliable motor can be used for driving mine pumps.

The pump must run day and night; the atmospheric conditions are very unfavorable; and the motor is often located in remote places where it can be inspected at infrequent intervals only.

**Hundreds of Westinghouse Motors have for years given thoroughly satisfactory service in mines.**

Their reliability, proved beyond question, is the result of experienced design, careful construction, and rigid tests after completion.

Westinghouse motors can be supplied for every kind and size of pump. To insure satisfactory operation, specify Westinghouse motor when ordering your pump.

**Westinghouse Electric & Mfg. Co., East Pittsburgh, Pa.**

Westinghouse Motor Driving Mine Pump

Illustration No. C-257

A Hayward Drag Scraper Bucket digging in "rotten rock." Note the angle at which it is digging and the pieces of rock in its wake, torn loose by the teeth before it settled to dig.

Illustration No. C-256 (Lower View)

This is a companion picture to Illustration C-257. The same bucket after the operation, filled with a good 1½ cu. yds. of "rotten rock," a very difficult material to dig. This bucket handled it without blasting.

**This 1½ cu. yd. HAYWARD DRAG SCRAPER BUCKET handles over 2 cubic yards of top soil each trip.**

Further, it will dig this load in less than twice its own length.

It never balks nor hesitates, but takes loam or "rotten rock" with ease—digging it without blasting.

Every connection flexible—not a single rigid bail in its make-up. Nothing to break as it lands on side or stomach. There is less strain on the operating machine, because the Bucket may be picked up as soon as filled—without dragging it "home." This new

## Hayward Drag Scraper Bucket

works perfectly at any angle. It requires but two men and less than three minutes' time to change from a hard to soft digging Bucket. Where other Buckets have cross bracing and hoods which prevent them from entering the material, the Hayward Drag Scraper has an open front so that in digging, large boulders and large rocks are easily handled.

Get the facts from us—say Pamphlet 582 on a postal.

## Won't Crack, Break or Lose its Insulating Value from Vibration or Rough Usage

The temperature of high pressure pipes soon dries out molded and ordinary pipe coverings. Then expansion and contraction of the pipes and vibration reduce the carbonate of lime (chalk) and other like materials with which these coverings are filled to a powder. This powder settles at the bottom of the canvas covering, leaving the top insufficiently covered, and gradually sifts through the canvas. Thus what little insulating properties they originally had are quickly lost.

## J-M Asbesto-Sponge Felted Pipe Covering

retains its high insulating properties indefinitely. Pipes covered with it can even be walked upon without injury. This is because it is made of many layers of fine paper, composed of pure, long-fibred Asbestos and a small quantity of granulated sponge. It has been found in perfect condition after more than fifteen years' service on underground pipes.

Can be taken off pipes and replaced without injury.

**Seldom on the Pay Roll  
Always on the Job**

## **Improved Wood Rock Drills**

Day in, day out, always, ceaseless drilling—drilling—drilling. That's a Wood Rock Drill! Rarely needs repairing; requires little attention.

Never, like poor drills, continually at the cashier's window, spending more and still more money.

The master mind that planned the first Wood Drill twenty-one years ago, is still overseeing every detail of its manufacture now. If we weren't progressive we could well say "Here we rest our case"—but we're not the "resting" kind.

Ours is the one drill that's "certain." The one drill you can depend upon. The one drill that carries a guarantee which means something; "We guarantee Wood Drills against any defects during the entire life of the drill. We guarantee Wood Drills to do more work, cost less for repairs, and stay on the job longer than any other drill on earth."

# "S-A" Belt Conveyors for Bedding Concentrates

The new "S-A" Unit Carrier has features of advantage which should be familiar to all mining men.

It is the strongest carrier on the market, and yet is lighter in weight than any other carrier of corresponding size.

The light weight and strength is secured by the pressed steel construction with drum type pulleys, mounted with double supports.

Dust-proof ball bearings eliminate the attention required by other carriers.

The carrier is almost frictionless and saves the belt.

Adaptable to all operating conditions.

## The "Labor Saver" gives Conveyor News

Tell us your name and the position you hold, and we'll send you this monthly magazine without charge. It's of interest to all mining men.

The application of modern methods in the handling of their ore has enabled the Cananea Consolidated Copper Company to place their low grade ore properties on a paying basis.

The latest conveying system installed has been applied to the bedding and reclaiming of concentrates. The concentrates are received in gondola cars, and in order that a uniform grade may be delivered to the furnaces, they are "bedded." A system of three "S-A" Belt Conveyors brings the concentrates from the gondola cars—the third conveyor on the bridge distributes over an automatic tripper on to the pile. A system of three other "S-A" Conveyors reclaims the ore and delivers to pockets above the furnaces.

Let our engineering board solve your conveying problems.

## Built on a Solid Base

### The Reputation of Prescott Mine Pumps

**Why? Because** the initiation of the business was not an accident of chance, nor a broadening out to embrace the mine pump field because it was attractive. **Read the Condensed History**

Corliss Cross Compound High Duty Mine Pumping Engine

From 1885 to 1894 Fred. M. Prescott dealt in mine machinery and supplies. Meantime mining practice was changing. The originally shallow mines grew deeper with attendant increase of water and fuel costs, creating the necessity of heavier and more efficient pumps. As builders of pumps Mr. Prescott represented could not see that their standard types were outgrown, he began to

build them for local trade. Their immediate success developed a demand that forced him to devote himself to their manufacture. Subsequent history is familiar—the growth of the business until it included the building of the most successful pumps in a wide range of patterns to meet every sort of mine service. This is well attested by our *Catalogue P 22-32*. It proves “Who builds the best Mine Pump? **PRESCOTT.**”

## No Other Pump Equals the Economy of the “American” Centrifugal as a Mine Pump

It combines the highest development of the centrifugal principle of pumping with greatest simplicity of construction.

Flowlines are worked out to the easiest possible curves and interior of casing and impeller are machined true and accurately adjusted, preventing back-flow.

There are fewest number of parts, all passages are cast in the casing and all parts are easily accessible without disturbing the pipe connections.

Our sinker and mine station pumps have many advantages over old-style plunger pumps for these purposes.

American Centrifugals are made in over 50 regular styles, backed by longest experience and largest output.

They are described in General Centrifugal Pump Catalogue No. 117, the most complete ever issued. Write for it.

# Hendy Mill Units

Usually, in the beginning, when the investment is small, it is necessary to employ machinery which does not require much outlay of capital.

Hendy mills are built as a system of units.

Hendy improved triple discharge two-stamp mills are the first of the units.

Their capacity is sufficient to warrant installation in a battery of two or three mortars for permanent work—all details are equivalent to our standard mills.

Once the mine proves good and you wish to begin operations on a large scale, this two-stamp mill simply forms the nucleus of your plant.

Many of our customers in different parts of the world have begun operations in this way—it's a good beginning.

*Illustrations and complete information concerning this two-stamp mill, as well as the larger Hendy mill units, will be found in Bulletin 113—send for it.*

Plain Whistle with Valve

### LUNKENHEIMER WHISTLES

produce clear, bell-like tones that can be heard for miles.

They are made in a large number of varieties—Single Bell having but one tone; Single Bell Chimes, or Three Separate Whistles on a Branch, both styles producing three distinct tones, and Variable Sound Whistles, provided with pistons from which any tone desired can be obtained.

Owing to the correct proportions of Lunkenheimer Whistles, they are very economical, as a very small expenditure of steam or air is necessary to obtain satisfactory results.

They are exceptionally neat in design, are very strong and durable, and satisfaction is guaranteed.

Specify and insist upon securing genuine Lunkenheimer make. Do not accept substitutes—they are never as good as the genuine.

Your local dealer can furnish them; if not, write us.

Write for 1912 catalogue.

## DRIVE YOUR TUNNELS QUICKLY and CHEAPLY

BY USING

### EXPLOSIVES

The driving of tunnels in ore mines can be accomplished at a considerable saving of time and cost of labor by resorting to the following Brands:

#### Forcite, or Repauno Gelatin Dynamite

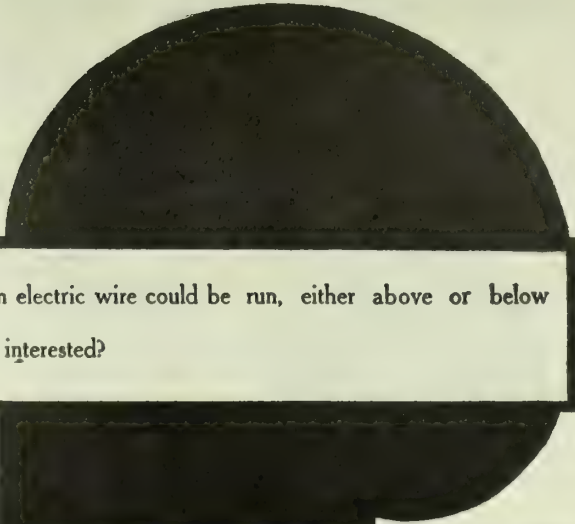

These explosives are noted for their rending power and the minimum fumes resulting from their detonation. If very hard rock is encountered, we recommend the loading of a few cartridges of Blasting Gelatin in the back of bore-holes with Gelatin Dynamite on top of them.

To be able to complete tunnels economically, you should use Du Pont Explosives exclusively. Just which one is best suited to the condition found in your mines may be learned by asking for High Explosives Catalog No. 119, or stating your problems to our Technical Division.

**Du Pont Powder Company**

WILMINGTON, DELAWARE

If you heard of a drill that could be installed anywhere that an electric wire could be run, either above or below ground, at less than one-third the cost of pipe lines, wouldn't you be interested?

If you learned of a drill that would actually save 70% to 90% of what you are now paying for power and at the same time advance your work faster, easier and better than ever before, wouldn't you be anxious to learn the particulars about it?

If we claim the Fort Wayne Electric Rock Drill will do all this and offer to send you a Bulletin that explains the design, construction, and operation of the drill, don't you think it would be worth while writing for it?

## Goodyear "Step" Concentrator Belt

The surface of the Gates Improved Step Concentrator Belt is composed of a series of transverse steps, with 'treads'  $\frac{1}{4}$  in. wide and 'risers'  $\frac{1}{32}$  in. high. When the belt is running on a concentrator the 'treads' are horizontal.

This design prevents the heavy particles of mineral from escaping down the belt by holding them on each step, until dense enough to discharge the sands, when, due to the combined motion of the machine and flow of water, they gradually travel toward the mineral discharge end of the machine.

With this belt it is almost impossible to overload a concentrator, because even if a few steps are overloaded, the lower part of the belt holds the minerals until separated. The efficiency of a machine equipped with this belt is therefore greatly increased, and produces cleaner concentrates.

Our patent edge is used on the Gates Improved Step Concentrator Belt. The edge will stand up in passing around drum, and will not crack.

## McCully Gyratory Crushers

Could ANYTHING be MORE CONVINCING of Their MERITS?

Of course these are exceptionally large jobs.

That is just why we mention them. There are a great many different contractors involved and it is evident how many of them agree as to which is THE crusher. Moreover it is for such large jobs that the greatest care is taken to select the BEST crusher. Only the best is good enough.

On small jobs this is not so important. But—we could go on and give a long list of smaller jobs where our crushers are the ONLY ones used.

If you want to know WHY the McCully Crusher is preferred to all others, send for our bulletin PM-432.

# CASE GASOLINE BURNER

GOODALL BROS., ASSAYING.

Helena, Montana, May 24, 1912.

DENVER FIRE CLAY CO., Denver, Colorado.

*Gentlemen:* We have been using your Case Burner 2", and find it the most comfortable burner we have ever worked with. After a month's service the plugs are still tight and there is no leakage. It is so far ahead of the ——— burner that there is no comparison. The other burners we don't consider at all.

Sincerely yours, GOODALL BROS. (by Herbert Goodall.)

### Have you ever considered using a locomotive crane at your mine or mill?

Being self-propelled and having complete rotation of the boom, it will handle all your ore and other material rapidly and at a low cost. The illustration shows a Brownhoist crane loading ore, 1½ to 3 tons at a load, with only one man, the operator, of the crane.

*Our catalog shows this crane in use at mines and mills. Write for it.*

### THE BROWN HOISTING MACHINERY CO. CLEVELAND, OHIO

### Quarrymen who have not used "BUSY BEE" HAMMER DRILLS would do well to inquire of those who have.

To break up boulders or large pieces of stone and for general cleaning up about a quarry, the "BUSY BEE" Hammer Drill is an indispensable tool. Over 200 feet of blast holes has frequently been drilled with one of these hammers in a day. Real economy in the quarry is attained where "Busy Bee" drills are used.

Full particulars are given in the "Busy Bee" Hammer Drill Bulletin. Send for it.

### S. S. & S. Dry Concentrating Table

Capacity three times that of the best types of wet concentrating tables.

Especially adapted to the treatment of refractory ores having close specific gravities.

The S. S. & S. System of dust control eliminates all dust made in dry crushing.

COMPLETE TESTING WORKS FOR ORE TESTING

## Kilker's Matte Tapping Car

THE CORRECT METHOD OF HANDLING MATTE

The 16 pans in this tapping car will hold 3,000 pounds of copper matte, yet they can be easily revolved with a bar and operated by one-man power. When a tap is being made the matte strikes in the successive pans and the entire mold is filled up by a series of layers of matte, which solidifies in thin layers, making it easy to crush for later operations.

It is possible to tape 3,000 pounds every 30 minutes. Dumping is accomplished by putting a bar under the back lug of pan and tipping it up slightly. The overbalance does the rest. Only a few minutes required for the entire car. Cakes are in simple form for handling. The first cost is low. It has been in use for years. It is durable, efficient and simple.

*Send for Descriptive Circular.*

### PACIFIC FOUNDRY CO.

18th and Harrison Sts., San Francisco, Cal.

## PACIFIC ROCK DRILL

MADE IN SEVEN SIZES

The distinguishing feature of this drill is the fact that the guide lugs on the cylinder and the corresponding seats on the shell are not in the same plane, thus absolutely preventing side play when the guides and seat become worn.

Send for our Circular 30 showing full details.

Low cost of up-keep.

Few wearing parts.

Light in weight.

Variable stroke.

Simple design.

### D. D. Demarest Co.

## ROOT WATER TUBE BOILERS

Metal prices were never lower than now. The necessity for every economy in mining was never more imperative. **A saving on your power cost will mean an increase in your mine profits.**

Needless to argue the superior economy of the water tube boiler over other types. Every engineer admits it—and profits by it where he can.

**You can realize Water Tube Boiler economy at your mine—no matter how inaccessible your location—by installing the Root Water Tube Boiler.**

For the Root Boiler is the only true Sectional Boiler on the market, breaking up into parts suitable for pack-animal transport anywhere.

With the high fuel costs prevalent in most mining districts, you **must** make the greatest possible amount of steam per pound of fuel burned.

With a Root Boiler, you will **not only** realize the highest fuel economy, but you will do so at the lowest cost for freight, transportation and erection.

## 35% Rock Drill Supremacy

### 35% Saving in Maintenance

**Because:** the Chicago Giant is better built. Special metals for particular parts. Better workmanship, better design.

**Because:** the Chicago Giant has simplified mechanism, positive valve motion, positive rotation, adjustable guides. The Chicago Giant makes a 35% saving in first cost. Prove this by getting our prices.

## Chicago Pneumatic Tool Co.

## When You Want a Pump

Give us an opportunity of showing you why you should purchase one of our outfits. We can supply you with a pumping outfit, no matter where or what you have to pump. Our pumps are practical, and are built so they have to give good service. They can't do otherwise. Give us a few conditions under which the pump must work and ask for Catalog "H."

An efficient pump for operation by any power, and a universal favorite among all pump users.

## THE POWELL "WHITE STAR" VALVE

Renewable, Reversible and Regrindable

The only valve on the market to-day combining the above features.

The White Star Renewable, Reversible and Regrindable Disc being made of a peculiar white bronze, will resist high temperatures and the wearing action of superheated steam.

The reversible and renewable features alone make it the most economical valve on the market.

Specify Powell to your jobber and insist on getting what you specify.

THE SLOGAN OF THE CAMERON—  
"CHARACTER: THE GRANDEST THING."

## Cameron Pumps

Regular Pattern

### WHAT AMOUNT DO YOU PAY FOR PUMP SERVICE PER YEAR?

The price of a pump divided by the number of years it gives efficient service—with the cost of power and repairs considered—gives a true estimate of its value.

Judged by this value Cameron Pumps are found to be the most economical and satisfactory you can buy.

There are excellent reasons for this: Simplicity of design, superiority of material, fewer working parts than any other steam pump made; no outside valve gear, and a compact, strong and durable construction.

All of these qualities are of intensified importance to the careful buyer of permanent pump equipment. If you want to pay the lowest price for efficient pump service be sure to install the CAMERON.

Cameron Catalog No. 18 illustrates and describes all types of Cameron Pumps. Sent on request to interested pump users.

## CHROME STEEL WORKS

CHROME, N.J., U.S.A.

# Forged Chrome Steel Shells for Long Service and Rings

"ADAMANTINE" Shells and Rings are hydraulic-forged and rolled from a solid Chrome Steel Ingot. This process forges the Ring from a solid mass, giving the Metal the greatest possible work with the result that we are enabled to produce a Shell which has all the elements necessary for long service, even wear and hardness and toughness combined.

TRADE  
ADAMANTINE  
MARK

For Wet or Dry Crushing—Shells for Cornish Rolls, Rings and Tires for Chilian Mills, Huntington Mills and Griffin Mills, etc., etc.

**Guarantee**—We guarantee that our "Adamantine" Chrome Steel Shells and Rings, will, at our price, prove more economical and satisfactory, by reason of superior service, as against any other make now on the market.

"Adamantine" is our registered Trade Mark. To avoid substitution order by that name.

Illustrated Pamphlet "Forged Shells and Rings" if you write.

## FOR THE MILLMAN

## PRACTICAL STAMP MILLING AND AMALGAMATION

By H. W. MacFarren

166 Pages

Indexed

\$2 Postpaid

Gives details needed in everyday work. The stamp-mill, its location, and design; the mortar, die, shoe, tappet, and cam; adjustment of height, order of drop, feeder, and screens; water supply and power; principles of amalgamation and treatment of plates; retorting; loss of gold, mill tests, and mill management; all these are treated in an illuminating manner by one who has himself solved the problems.

MINING AND SCIENTIFIC PRESS, 420 Market St., San Francisco  
THE MINING MAGAZINE, 819, Salisbury House, London, E. C.

## POSITIONS WANTED

The cost of advertising for positions wanted is 2 cents per word per insertion. Minimum order 50 cents. Replies forwarded without extra charge. Remittance must accompany order.

**CYANIDE-MAN** desires position, foreign country preferred; technical graduate; 8 years Mexican experience; familiar with most modern practice and machinery; twice in charge successful plants; interested in the work and would prefer employment under technical management. Address Box 995, this office.

**MILLMAN**, amalgamator, concentrator, cyanide-man, assayer, surveyor, draughtsman, superintendent; graduate University of California; 15 years experience, seven Mexico; position desired any capacity good company. M. A. KNAPP, 1732 Webster St., Oakland, Cal.

**ELECTRICIAN AND MECHANIC**, college educated, 33 years old, ten years practical experience erecting and maintaining electrical and mining machinery, desires position with mining company; have just finished the installation of a large gas electric plant in Mexico; references furnished. Address Box 993, this office.

**POSITION WANTED**—By young, sober, experienced assayer and surveyor, familiar with cyanide testing; salary and location secondary importance; in position to move quickly. Address Box 994, this office.

**WANTED**—By an all around diamond drill man, a position with a reliable company; can furnish good references; have had twelve years experience. Address Box 992, this office.

**MINE MANAGER**, accustomed to large organization, details, severe conditions, close margins, milling, amalgamation, and cyanide; family. Address Box 987, this office.

**ASSAYER AND CHEMIST** desires position with reliable company; has been employed in some of the biggest smelters and cyanide plants as lead chemist and assayer; 38 years of age and married; best of references can be furnished. Address Box 989, this office.

**EXPERIENCED METALLURGIST** desires change; has had exceptional experience in cyaniding silver ores and concentrates; thoroughly familiar with latest devices and best practice in amalgamation, concentration, and cyanidation; have made good in operating plants economically and efficiently; best references. Address Box 990, this office.

**WANTED**—By a practical all-round miner, position as foreman of mine; am capable of handling almost any kind of work pertaining to mining; 25 years experience in mining and engineering; good in hydraulics (not a technical graduate from mining school); will go any place, from Alaska to South America. Address Miner, 1197 E. Yamhill St., Portland, Ore.

**MINING ENGINEER**, technical education, eight years practical experience in Western States, Canada, Mexico, and South America, in all capacities from mucker to manager; thorough knowledge of underground work, cyaniding and milling; speaks Spanish; desires position; testimonials from previous employers and engineers of repute. Address Box 957, this office.

**SUPERINTENDENT** or assistant superintendent, surveyor, assayer and cyanide chemist; a technical graduate, Dept. U. S. Mineral Surveyor; A-1 underground surveyor and map maker; 6 years experience; salary reasonable. Address Box 944, this office.

**POSITION DESIRED** as superintendent or manager; technical graduate with ten years of practical experience in mining gold and silver; also copper, lead and zinc; good organizer and expert metallurgist; successful with low-grade ores; speaks Spanish; first-class testimonials. Address Box 929, this office.

## FOR SALE

Five gold quartz claims; good prospect, plenty of timber; three miles from Klamath river and near Gortville, Siskiyou county, California. For further particulars, address or see E. B. WHITMAN, 502 Wells Fargo Bldg., San Francisco.

## FOR SALE

New 6 H.P. Atlas Standard Gasoline Engine complete with attachments for operating on kerosene. Can be inspected in San Francisco. Will sacrifice for quick sale.

ATLAS ENGINE WORKS,  
Indianapolis.

## DIAMOND DRILL CONTRACTOR

M. A. SHAIRP, Box 522, San Francisco

I am prepared to undertake contract drilling with my own outfit. Have had 13 years' experience in diamond drilling and can refer to many mining companies.

## NOTICES OF RECENT PATENTS

Among the patents recently obtained through Dewey, Strong & Co.'s Scientific Press United States and Foreign Patent Agency, the following are worthy of special mention:

**DENTAL CROWN AND BACKING**.—Robert E. Campbell, Berkeley, Cal. It is the object of this invention to provide a backing for a dental crown which is so designed and constructed as to form a substantial and rigid support for a porcelain crown, or the like, and which is so arranged that the crown may be easily and quickly mounted thereon.

**AMUSEMENT APPARATUS**.—Douglass H. Cleghorn, Oakland, Cal. This invention relates to a new amusement apparatus, the object of which is to create a new sensation by carrying passengers in carriages on a circular track which has sudden dips and rises.

**RAILWAY-RAIL CHAIR**.—John W. Swales, Fruitvale, Cal. The object of this invention is to provide a means for securely holding railway rails in place upon the ties or sleepers upon which they are carried.

**REVERSIBLE HYDRAULIC CLUTCH**.—Peter English, San Francisco, Cal. It is the object of this invention to provide a means for transmitting motion from a driving shaft to the shaft to be driven, which will permit of the speed of the driven shaft being varied to any desired extent.

**CURTAIN AND LIKE DISPLAY DEVICE**.—Ferdinand Frank, San Francisco, Cal. This invention relates to an apparatus for displaying curtains and light goods which are usually carried in rolls or sheets, and which must be unrolled and exposed for display purposes.

**CANE-CUTTER**.—Elmer E. Paxton, Honolulu, Hawaii. It is the object of this invention to provide an apparatus which is especially designed for cutting sugar cane or like stalks which it is desirable to sever closely to the ground.

# FOR SALE

We offer for one of our clients a mill with  
 complete gold mining machinery equipment,  
 now located on the Fanny Edell property about  
 15 miles from Cle Elum, Kittitas County, Wash-  
 ington, either completely as it stands or will  
 sell the machinery separately. The mill has a  
 capacity of making a product of 40 tons per 24  
 hours that will pass 40 mesh screen. The ma-  
 chinery is in first-class condition, practically  
 new, as it has hardly ever been used. The prin-  
 cipal items of machinery are as follows: one  
 4 x 8 grizzly, one 7½ x 11 Samson crusher, one  
 Elspass mill and feeder; one 50-ton Pierce  
 amalgamator and car; two Standard concen-  
 trators; one 30 H.P. automatic engine; one 40  
 H.P. boiler; one 7 H.P. vertical engine, Stand-  
 ard heater, copper plates, belting, shafting, etc.  
 The original cost of the mill and machinery  
 about \$11,000.00. Any good reasonable offer  
 will be accepted. **SHORT & GLEYSTEN,**  
 Cle Elum, Wash.

# Yellow Strand Economy

Yellow Strand is the most economical wire rope in the world for heavy work because it lasts longest.

It lasts because it's made to last, from special imported steel wire of 240,000 to 260,000 pounds per square inch tensile strength.

Over a third of a century of wire rope making experience has taught us how to lay that high class wire into rope that combines unusual flexibility and elasticity with its tremendous strength.

"Yellow Strand in your rope Means Yellow Gold in Your Pocket"—always—every time.

## B. & B. Aerial Wire Rope Tramways Save Labor, Time, Money

A B. & B. Two-Bucket Tramway saves Logansport, Ind., 94 per cent of its expense for hauling coal to its lighting plant and pumping station. The haulage cost by wagon was 50 cents per ton. Now it is only 3 cents. And this cost includes labor, power and depreciation.

Ask our Tramway Department for further details.  
Write for Catalog No. K45.

## EDITORIAL

VICTORIA, the pleasant and attractive capital of British Columbia, is to entertain the Western section of the Canadian Mining Institute, September 18.

ARIZONA recently enacted a law making a mining property, operated under a lease, option, or otherwise, responsible for all bills for labor involved in working the property. Similar bills have been enacted elsewhere, and certainly the laborer often needs better protection. The Supreme Court of Wyoming has, however, held that such a law is only constitutional when it applies to all classes of industry.

CEMENT-MAKERS did not have a good year in 1911, according to figures collected by Mr. E. F. Burchard, of the United States Geological Survey. While the total output of the United States was 79,547,958 barrels valued at \$66,705,136, the actual increase, 1,500,000 barrels, was the smallest in 13 years. An interesting fact shown by the statistics is that California now ranks third in production and second in value of output.

SAN FRANCISCO engineers have long had the pleasant habit of lunching together frequently. This has now crystallized in the formation of an Engineers Club, which is to meet at luncheon at the Palace hotel on Tuesdays. Mr. C. W. Merrill has been chosen as first president of the club. Associated with him on the executive committee are Messrs. A. H. Babcock, M. H. Peck, A. M. Hunt, and H. Foster Bain. It is hoped to make the club an effective agency for promoting mutual acquaintance and a pleasant medium for the entertainment of visiting engineers.

ADVICES from Washington announce the serious illness of Mr. W. J. McGee, long prominently connected with the United States Geological Survey and the Bureau of Ethnology, and now soil expert in the Department of Agriculture. Mr. McGee's many friends will hope that the account of his poor health may prove exaggerated. A strong, self educated man of vigorous intellect and philosophical bent of mind, he has contributed notably to the progress of geology and related sciences, and at the same time his friendly interest and quick sympathy have stimulated many a young scientist to better work. Impatient as reformers usually are, he has given a good account of his talent.

EFFORT is being made to revivify the California Miners' Association, and a meeting of the executive committee has been called at the St. Francis hotel July 15. The Association was for years a powerful influence voicing the needs of mining industry of the state. It has a long and honorable record for good work, but in recent years has lain dormant, only a skeleton organization being maintained. The approach of the time of holding the Panama-Pacific Exposition and the desirability of assuring an adequate exhibit of Western minerals and mining methods leads the officers to believe that the general work of the Association should be resumed, and all those familiar with its history will wish them the fullest measure of success.

**T**HE fiscal year at Washington closed with a surplus of \$32,000,000, as against one of \$45,682,000 in 1911. Except for the failure of Congress to pass usual appropriation bills there would have been a deficiency. It is interesting to note that customs yielded \$310,000,000, internal revenue \$292,000,000, and the corporation tax \$27,000,000.

**S**MOKE problems are attracting large attention throughout the coal-burning territory, but nowhere is a more determined effort being made to overcome the nuisance than in Pittsburg, long known as the 'Smoky City.' With rare good sense, foundation for success is being laid in broad research. A fund has been placed at the disposal of the University of Pittsburg and a special staff has been organized to carry on the work. At present the investigation is being conducted by a force of twenty-five, of which seven are giving their entire attention to this task. Some of these men are studying the effect of smoke and soot on the atmosphere, on the weather, on plant life, on buildings, on the public health; some are investigating the economic damage done by smoke and soot; others are making a detailed study of the mechanical devices for preventing or abating smoke; and still others are inquiring into the chemistry and physics of smoke and soot, into the laws concerning the smoke nuisance, and into the history of the subject as a whole. Recognizing the interest in the smoke problem manifested by a large number of American cities, and in response to inquiries that have recently been made, it has just been announced that the members of this staff are prepared to lecture upon various phases of the problem upon request. Those interested should apply to Mr. R. C. Benner, who has general charge of the investigation.

**C**OMMERCIAL attachés are utilized by European countries as a means of detecting trade opportunities before they have been utilized by rival nations, and an important part of the success attained by Germany in foreign trade is due to her successful use of such means. Recently the Associated Chambers of Commerce of that country have suggested that commercial attachés should be stationed at consulates, in order to be in closer touch with trade than is possible at the great capitals, where industry is apt to be subordinated to politics, and the suggestion is typical of the spirit of intelligently directed effort which characterizes development of German trade. Example is more stimulating than precept, and, by the initiative of Messrs. H. A. Wheeler and J. H. Fahey, the American Association of Commerce and Trade has been formed in Berlin to "provide a national clearing house for the development and consideration of business opinion and to secure united action upon questions affecting the commercial interests of the United States. Only questions of national importance shall be considered." The Association should be able to accomplish much, and it is to be hoped that the movement will receive the support it deserves. The great trade opportunities of the future lie in the Orient, not in Europe, and it is discouraging to contemplate the trade relations between the United States and Oriental countries. In contrast with Germany, where consuls are, in many instances, men possessed of expert knowledge concerning trade conditions, American consuls in the Far East are, though otherwise competent, frequently devoid of more than a vague general knowledge of industry and the conditions which govern it, and no attempt is even made to supply the deficiency by the appointment of commercial attachés, though even such small European countries as Sweden maintain commercial attachés at Peking and Tokyo. When American trade with the Far East is fostered by intelligent and well directed effort a better showing in completion with European countries may be expected.

**E**XTENSIVE preparations are being made for the twelfth session of the International Geological Congress which is to be held in Canada next year. Excursions have been arranged preceding and following the meeting to all parts of the Dominion, from Nova Scotia to British Columbia, and an attractive program is being arranged. The special topics proposed for discussion include: the coal resources of the world; differentiation of igneous magmas; the influence of depth on the character of metaliferous deposits; origin and extent of pre-Cambrian sedimentaries; subdivisions, correlation, and terminology of the pre-Cambrian; to what extent the Ice Age was broken by interglacial periods; the physical and faunal characteristics of the Paleozoic seas with reference to the value of the recurrence of seas in establishing geologic systems. The International Congress is a widely representative body of great usefulness. At the last session, in Stockholm, the various countries were represented as follows: Algeria, 3; Germany, 161; Argentina, 2; Australia, 2; Austro-Hungary, 64; Brazil, 1; Bulgaria, 2; Canada, 6; China, 1; Denmark, 22; Egypt, 3; Spain, 9; United States, 63; France, 53; Great Britain, 44; India, 1; Italy, 30; Japan, 6; Mexico, 7; New Zealand, 2; Holland, 13; Portugal, 4; Rumania, 9; Russian Empire, 56; Sweden, 134; and Switzerland, 16. It is anticipated that about 1000 persons will take part in the Canadian meeting. Two previous sessions have been held in America, one at Washington in 1891 and another in Mexico in 1906. Both meetings were notably successful and it is anticipated that that to be held next year will surpass them. A copy of the preliminary circular and program, in French or English, may be obtained upon application to Mr. R. W. Brock, general secretary, Victorian Museum, Ottawa, Canada.

**P**ATENT law is again thrown into controversy by the decision of the Massachusetts Supreme Court in the case involving the United Shoe Machinery Company. It was here held that although the question of whether the company is "an illegal combination in restraint of trade and has monopolized trade and commerce between the several states," must be decided ultimately by the United States Supreme Court, "no word or phrase in the Sherman anti-trust act reveals an intent to exempt the owners of patents from its sweeping provisions against monopolistic combination. The conclusion seems to follow that the comprehensive condemnation of the act against every person who monopolizes interstate commerce by combination with the others includes holders of patents as well as others." The company involved was one formed to perfect and maintain a monopoly by use of patents. There have been many similar cases, such as the reputed fact that it is impossible to purchase machinery for use in a steam laundry except the purchaser agrees to maintain a certain standard schedule of retail prices. It was fear of the extension of such a policy rather than any desire to rob inventors of just reward for their skill, that led to the popular outcry against the recent decision of the United States Supreme Court. If a clear line can be drawn between proper and improper use of patent monopoly, and the contention of the Massachusetts court sustained, there is no valid reason for objecting to the doctrine laid down by the Supreme Court. It is one thing to maintain that the maker of a manfolding machine may take his royalty in the form of a legitimate profit on a required ink, and another to insist that no one shall buy a mangle unless he agrees to charge three cents for each collar laundered. Patents are sound in principle, and in any legitimate operation of the patent law the patentee needs, just now, more protection than the public; but patents should not be used to make legal what would otherwise be an illegal monopoly.

**D**RILLING contests are regularly a feature of Fourth of July celebrations throughout the West, and even across the Pacific the custom has spread. At Tonopah this year Page and Pickens established a new record by drilling  $45\frac{7}{16}$  inches in Rocklin granite in 15 minutes, striking an average of 66 blows to the minute. Lundquist and Dahlen, of Victor, Colorado, drilled  $41\frac{7}{16}$  inches, and Porter and Goddard, of Oatman, Arizona,  $38\frac{7}{16}$ . At Lowell, Arizona, a shoveling contest was held, the task being to shovel two tons of ore over a partition three feet high. The prize of \$100 was won by Henry Arnes, who completed the task in 8 minutes. His nearest competitor, Frank Travers, was 26 seconds slower.

### Lead Mining in Missouri

Statistics of metal mining in Missouri in 1911, compiled by Mr. J. P. Dunlop of the United States Geological Survey and summarized on another page, invite comment. The total value of the state's production of lead, zinc, copper, and silver in 1911 is placed at \$30,171,311; a very considerable sum. It is interesting to note that toward this total, silver contributed \$26,430 and copper \$80,051, and that production of both is increasing. Missouri mines now yield 49,867 ounces of silver and 640,411 pounds of copper, which fact will come as a surprise to those who think of Missouri as only a lead-zinc state. It is true that the most important contributions to the world's metal production now being made by Missouri are in the form of zinc and lead. In zinc the state has long ranked first, and shows no signs of impending loss of standing. In lead Missouri has held first place since 1907 when Idaho was passed in the race. Missouri lead mines have been known since the earliest settlement of the Mississippi Valley, but with the development of the silver-lead deposits of the Rocky Mountain regions attention was diverted from them and it was thought that their importance had ceased. This proved to be an error. When the price of silver dropped one-half, a new period of development began in the lead fields of the Mississippi Valley, and they now occupy their old place of first rank.

The greater part of the lead output of Missouri comes from the southeastern district. In 1911 the crude ore mined there equalled 3,974,712 tons and in the central and southeastern districts together, 219,145 tons of concentrate was produced. Since the output of the central Missouri district is relatively insignificant, this means that the five big companies operating in the Flat River district furnish nearly half the lead produced in the United States. The lead content of the crude ore in this district is 3.7 per cent. From this is made a concentrate containing 67.3 per cent lead and worth \$46.94 per ton. The yield of concentrate from the crude ore equals 5.5 per cent. These are Mr. Dunlop's figures and are based upon returns from all the companies. One concern is, however, known to work ores averaging about 3 per cent lead and worth, accordingly, about \$2.40 per ton in the ground. Even at this there is a profit since the saving is about 85 per cent and the operating cost, roughly, \$1 per ton. Some of the Missouri companies have had a long struggle but all are now making money. While they do not distribute stockholders reports it is known that one cleared about \$750,000 last year, another \$500,000, and that others did proportionately as well. Though the plants are large they are simple and the investment charge, other than for land, is not unusual, taking into account the fact that each company, except the Doe Run which is affiliated with the St. Joseph, owns its smelter and markets its own metal.

It is interesting to compare these figures with those of the Bunker Hill & Sullivan Mining & Concentrating Company,

operating in the Coeur d'Alene district of Idaho. This great company has mined to the close of 1911, 4,883,468 tons of ore having a gross value of \$47,581,988 and has made an operating profit of \$19,009,363, paying dividends to the amount of \$12,701,850. Roughly the ore is worth, gross, \$10 per ton; it costs \$6.75 per ton, including freight and treatment; and the profit has been a trifle over \$3.25. The recoverable value of the ore in 1911 averaged \$7.55, of which \$1.49 was due to the silver content. The ore is much more complex than in Missouri, milling costs more, and the tailing losses are higher. The gross value per ton of Coeur d'Alene shipping ore and concentrate was greater than that of a ton of Flat River concentrate, the figures being \$50.14 and \$46.94 respectively, the difference being due to the silver content. Operating costs at the Bunker Hill & Sullivan mine are \$2.03 per ton; about twice as large as in the best Missouri practice. The ore, however, is richer; containing 9.59 per cent of lead and 3.81 ounces of silver as against 3 to 3.7 per cent lead and no silver at Flat River. Freight and treatment charges are much higher in the case of the Idaho ores than in that of those from Missouri. Another striking difference is in the character and form of the ore-bodies in the two districts. In Idaho the lead is found, in the form of galena mixed with other sulphides and carbonate of iron, metasomatically replacing quartzite along fault fissures. In Missouri the galena, with only slight admixture of other sulphides, occurs impregnating nearly horizontal beds of dolomite of great thickness and extent. The galena shows a marked preference for certain layers and for beds of peculiar physical condition and chemical composition, and its distribution is, in detail, extremely irregular. In Idaho it is possible, and customary, to develop and carry large ore reserves; that of the Bunker Hill & Sullivan company is now estimated at 3,521,050 tons. In Missouri, in a large way, there are no reserves and a steady output is maintained by keeping open a considerable area of 'face.' The conclusion should not be drawn that the companies operate 'from hand to mouth'. In fact they have in each case excellent assurance of long continued production, but this is not in the form of proved ore reserves. Since 1867 the diamond-drill has been commonly and largely used in this district. It was in truth the application of the drill that made possible all the modern development. It is not customary to figure in tonnage the proved or probable reserve found by drilling, for the reason that experience has shown that individual holes are extremely deceptive. Conditions are not comparable with those in copper mining where great confidence has come to be felt not only in the general but the specific results of drilling. In Missouri the character of the rock, especially the content of organic matter, is often as significant as the actual amount of lead present. Drilling here is of the greatest service in showing the general trend of the orebodies but not their actual content. One of the most capable and successful engineers who has worked in the district came, in time, to rely much less on the drill than on constant study of the face of the mine, calmly confident that the ore was continuous over large areas in some direction and could be followed underground. The orebodies are large and stopes are acres in extent; the ore is simple and the conditions for working excellent; fuel supplies, and labor are near at hand; and there is a ready market for the output. All these factors have enabled the Missouri companies, with a leaner ore and no silver, to gain upon their capable and energetic competitors in the West, and no one even superficially acquainted with the district can doubt that the lead industry that began when the Spanish first hunted metal for making bullets, will continue for many years to contribute to the national wealth.

## Veta Colorado Mill and Cyanidation Plant—II

By BERNARD MACDONALD

(Continued from page 4.)

### COMMENTS AND CRITICISM

In the first part of this paper\* I gave an outline of the flow-sheet or travel of the ore pulp and solution in treatment through the mill of the Veta Colorado M. & S. Co., at Parral, Mexico. I propose now to submit comments and criticism of the millsite, machinery, and practice.

*The Millsite.*—The selection of a site for the erection of a milling plant is of fundamental importance, and the greatest care, considering all the factors bearing favorably or adversely on the economy of future operations, should be intelligently and carefully exercised before making the final location. The same is equally true and of only relatively less importance with respect to the sites of all appurtenant buildings such as power-house, machine-shop, precipitation-house, warehouse, and assay office. Before the grade stakes are finally set, the designing engineer should have a clear comprehension of all the factors commercially affecting future operations, and from them work out a favorable balance for the site to be chosen. The selection of a site that is ideally perfect is impracticable, even in the most favorable localities, but existing conditions should be so weighed and balanced that the best site possible shall be chosen. The preliminary investigation and study necessary for this purpose is not always given by the designing engineer. It frequently happens that the site is arbitrarily selected by those who have little or no experience in mill construction or operation, and the engineer is left to do the best he can with the site so selected. Be this as it may, the fact remains that serious errors in the site of the mill or the accessory buildings exact their toll from the beginning of operations.

These reflections have been inspired from observations covering milling plants in general and not alone from the site selected for the Veta Colorado mill, although the site of that plant was not the best that could have been selected. The site for this mill was chosen too far down the hillside (a mistake frequently made), whereas, with a few minor disadvantages, completely overshadowed by general improvement in facilities for construction and operation, the mill might have been placed from 50 to 100 ft. higher. Such a site would have saved considerable expense in grading and retaining walls for the mill benches and in the disposal of the tailing of the ore treated, and the plant would have been more accessible for construction and operation.

In the design of the plant the old idea of placing the precipitation-room at the lower end of the mill was adopted. The result of this, coupled with the necessity of securing flow grades on the hillsides for the several benches of the plant, caused it to be stretched out so that it occupied a length of over 500 ft. from the crusher-bin to the precipitation-house. Notwithstanding this length, the site for the precipitation-house, and the sump tank and pump-house adjoining measuring 80 by 150 ft., had to be blasted out of the solid rock to an average depth of 12 ft., and, to provide floor drainage, a small tunnel had to be run from the bottom of this grade to a nearby creek. The precipitation-house, as designed and built, was 75 by 100 ft., just twice the size required, and at the place selected it was the most distant of all of the mill buildings from the offices and living quarters of the American employees, which made its supervision and protection more difficult.

In completing the plant, I seriously considered abandoning the use of this building for precipitation and the

erection of a new one on the patio at the head of the mill, where it would have had all the advantages of being close to the company's offices and the living quarters of the American employees, but as the house had already been substantially built of masonry, floored with cement, and the sump tank and return pump erected, the expense deterred me from doing so. Had the mill been placed higher on the hillside, the steeper contour would have provided for closer building of the several plant units, saved hundreds of feet of piping, and thousands of dollars in grading, besides affording better accessibility for supervision and more economical conditions for operation.

*Power Plant.*—The placing of this plant, and the design of its machinery could have been improved. It was built close to the mill, to which fuel had to be hauled from the railroad terminal, and the boilers supplied with mine-water carrying deleterious solids in suspension, while, with a 7-mile transmission line, it could have been built at the junction of two railroads where fuel would have been cheaper and plenty of clear water for the boilers available. And, for some reason hard to explain, the electric generators and the mill motors were designed for a 25-cycle current, a design at variance with common commercial practice. A 60-cycle electric plant was in existence at the time, designed for the sale of current to users in the district, and, at the present time, a 15,000-hp., 60-cycle, hydro-electric plant is bringing in its lines to the district to dispose of its power to the mines and mills. This power cannot be used in this plant without the intervention of 'frequency changer' and a corresponding consumption of power.

*The Rock-Breakers.*—As already stated, these are of the 'Australian type', which in operation close their jaws and crush the rock on the down-throw of the pitman, instead of on the up-motion as in the ordinary type. This antipodean type may work satisfactorily in Australia, but as designed for this plant it did not do so. The force exerted in crushing the rock on the down-thrust of the pitman reacted upwardly on the bearing boxes of the fly-wheels, loosening and frequently breaking the stud-bolts that held down the caps. The keeping of the toggles in adjustment was also much more difficult than with the ordinary type of rock-breaker.

*Mortar Foundations.*—These were built of concrete in separate blocks for 20 stamps at some time before work was suspended in 1907. I found these blocks cracked horizontally from end to end, the cracks being 6 to 12 in. apart, so that, at places, the top layers could be easily lifted by driving a gad in the cracks. I puzzled over this problem for some months pending the arrival of the mortars from the factory, and finally reached the conclusion that these cracks were due to one or more of the following causes: (1) the concrete was laid in layers and each layer allowed to dry before the next one above was laid down, the junction of the two contiguous layers constituting a line of weakness along which the unequal shrinkage of the dry and wet concrete was manifested in the cracks; (2) the sand in the different layers of concrete differed in character and quantity; (3) the frequent but erroneous practice of putting a thin leveling layer of neat cement on top of the block, instead of laying the block a trifle high and bringing it to proper level with a chipping tool. It was evident that the foundation blocks would crumble under blows at the stamps unless something was done to make the layers cohesive, for even the vibration of the blow of a sledge at one end of a block could be plainly felt at the other. To dig out the foundations and put in new ones, it was estimated, would have cost \$5000. This

\*See *Mining and Scientific Press*, July 6, 1912.

would have been safe, but that portion of the mill building was roofed and sided with corrugated iron and would have had to be stripped, as blasting would have been necessary in order to get out the deeper sections of the blocks. I finally concluded to have the blocks drilled with vertical holes to the depth of 30 inches, 30 holes under each two mortars and the shoes of the battery posts, and dropped into each hole a piece of  $\frac{7}{8}$ -in. octagon drill steel 30 inches long, around which was poured melted sulphur until the hole was filled level with the top of the block. After this there was no vibration felt under the blows of the sledge-hammer, and the rubber pads were put on and the mortars bolted down. On two of the blocks the top leveling layer of concrete ranging from  $\frac{1}{4}$  to  $1\frac{1}{2}$  in. crumbled off. From these I removed the rubber pads and wedged up the mortars to the level and tamped the space between them and the concrete solid with 'rust joint.' The result was satisfactory, as none of the foundation blocks showed any signs of weakness under operation.

**Concentration.**—The mill is equipped with 24 concentrating tables, which were put into service when operations began. Owing to the fact that the dump ore to be treated was the ferruginous oxidized low-grade material discarded from the ore previously mined from the upper levels, and that most of the other ore treated in the mill was of the same character, it was not practicable to make a clean grade of concentrate that could be profitably shipped to the smelters. After tests showed that better commercial results could be obtained from cyaniding the pulp without concentration, the tables were left idle and the pulp treated entirely by cyanidation. The concentrators remain in place ready to be started if complex sulphide ore is found in the deeper levels.

**Tube-mills.**—These measure 5 by 14 ft. and were originally designed to be driven by 30-hp. motors, but before starting I substituted 40-hp. motors, and even these had barely enough power to start the loaded mill from rest without reverse swinging. The spur and pinion gearing by which the motors operated the mill, proved not to have sufficient strength for the strains of operation, and after a couple of months' use three of these broke and were replaced by belt pulleys. The motors, when connected by belts, started the tube-mills with greater ease than when previously connected by spur-gearing.

It will be interesting to millmen to know of a little device by which I improved the grinding capacity of the tube-mills and lightened their running load. The discharge openings of the tube-mills were of 7-in. diameter and the pebble charge came up to the bottom of these openings, or  $3\frac{1}{2}$  in. below the longitudinal centre of the mill when at rest. I reasoned that if the discharge opening was smaller, so the mill could be loaded with pebbles until the longitudinal centre line of the mill was reached, this load would be easier started and better grinding would be done. To test this idea, I had a wooden plug 8 in. long turned on the lathe to the exact fit of the discharge opening and a  $1\frac{1}{2}$ -in. hole bored through the centre line of the 8-in. dimension. This plug was driven snugly into the discharge opening and the mill filled with pebbles an inch or so above the centre. The result was very gratifying, the mill was easier to turn over from rest and to run than with the lower charge of pebbles, and the grinding was better. Since this time I have recommended this in other mills, where it showed similar favorable results.

**Agitation Tanks.**—As stated at the beginning of these notes, the plant, as originally designed, provided for the dual treatment of the pulp as sand and slime. For the

agitation of the slime, tanks 25 ft. in diameter by 12 ft. high equipped with stirring arms were provided in the original design and in 1907 two standard Pachuca tanks 25 ft. in diameter by 45 ft. high were purchased. Most of the material for these tanks had reached the site, but none of them was erected.

For some years previous I had been developing and experimenting with a system of pneumatic agitation with the object of overcoming the defects of the Pachuca tank system, namely: (1) The uneconomical shape of the tank, having small diameter and great height, which provided small holding capacity per pound of steel employed in the construction; (2) the high consumption of compressed air for the work done, and the trouble and expense for operating the rubber sleeve air nozzle; (3) the vertical

PACHUCA TANK.

PARRAL TANK.

settlement of the pulp immediately around the central lift-pipe and the consequent imperfect mixture of the solid and solution constituents of the pulp charge around the side of the tank.

By experiments based on scientific principles, I had developed a system which worked out satisfactorily in a small way and promised to eliminate the defects above mentioned, and now the opportunity of applying it on a large commercial scale was presented. But what were to be the dimensions of the first 'Parral tanks' to make the best compromise of the various conditions existing at this plant? The factors to be equated in the compromise were: (1) my former ideal of an agitation tank to be of such dimensions as would give the greatest holding capacity per pound of steel used in its construction; (2) the height of the two standard Pachuca tanks, to be units in the series, the steel plate for which was in stock; (3) a large quantity of steel plate shaped for the original agitation tanks 25 by 12 ft. which was in stock; (4) arrangement of tanks suitable for either the individual or continuous processes of treatment as would prove best under experiment; (5) the original design to make the plant's capacity 500 tons per day to be carried out so far

as the machinery and material in stock would permit.

The compromised design and dimensions of the agitation tanks under these conditions resulted in a battery of tanks consisting of the two Pachuca, each 15 ft. in diameter by 45 ft. high, and five Parral tanks, each 25 ft. in diameter by 42 ft. high. The Pachuca had a holding capacity of 83 metric tons each and the Parrals 250 metric tons each; the pulp consisting of two parts by weight of solution to one of the dry solids. With the exception of one of the Pachuca tanks, which was set apart as a storage tank for the wash-water required for the filter-presses, these tanks were 'piped' top and bottom so as to be operated by either the individual or continuous agitation systems as might be demonstrated by test to be preferable. The Pachuca tank was equipped in the usual way with the central transfer pipe, 16 ft. diameter, provided with the 1½-in. pipe with rubber sleeve nozzle for the introduction of compressed air as furnished by the manufacturers, and the Parral tanks were equipped with four 12-in. transfer pipes, each of which was provided with a 1-in. compressed-air pipe equipped with a ball-valve nozzle. Operation was commenced and continued one month by the continuous process of agitation treatment and then changed to the individual process. So far as the extraction went, there was no difference shown by either process over the other, but on account of its greater economy and simplicity of operation, the continuous process was adopted after the tests.

*The Pachuca and Parral Systems.*—The Pachuca tank here gave as favorable results as usual, and, in comparison with the Parral tanks,

"I could have been happy with either,  
Were the other dear charmer away."

However, in this case, there was a decided difference between the charmers. So far as it was possible to determine the amount of air consumed in the tanks operating side by side, treating pulp of the same specific gravity, by the degree of valve openings on the compressed-air supply pipes of the same diameters, there was no greater consumption of air in agitating the Parral tank holding 250 tons than in agitating the Pachuca holding only 83 tons. Besides, the rubber sleeve nozzle in the Pachuca tank gave considerable trouble in starting up agitation after the compressed air was shut off for any reason, while, in the Parral tanks under the same condition, the ball-valve nozzles would start up agitation promptly without trouble. After the month's run, when the change was made from the continuous to the individual system of agitation, the rubber sleeve was found to be frazzled and to have lost its elasticity. At this time the 1-in. air-nozzle ball-valve was attached to the end of the 1½-in. pipe in the Pachuca tank, and afterward there was no more trouble in starting and the agitation was equally active,

with appreciably less valve opening. The following letter from D. S. Colland, assistant to C. W. Van Law, director for the Compania de Real del Monte y Pachuca, will be interesting as corroborative evidence on this point. It relates to experience at Pachuca in February 1912:

"Just a word regarding the installation of ball-valves in our Pachuca tanks. Before the receipt of your letter, accompanied by the 1-in. valve, we had already tried out the ¾-in. that you had left here. As you know, the valves we have always used are the rubber sleeves outside of 1½-in. air pipe. This pipe was reduced at the bottom of the tank for the ¾-in. valve and all the air turned on at the 1½-in. valve at the top. This resulted in the rising of the pulp in centre column but 2 in., the air bubbles simply forcing their way through the thick slime. Upon receipt of the 1-in. valve it was connected in the same manner and it worked excellently. The 1½-in. air valve at top of tank is opened about three-quarters of one turn for all the rubber sleeve valves, and the ball-valve has been operating now nearly a week, giving entire satisfaction. On last Friday the power was interrupted several minutes. The four tanks operated with rubber valves had to be opened full to start them, while the valve on the tank equipped with ball was not touched. As soon as the air-pressure came on, this tank began agitating exactly as before interruption. The slime during the test has been approximately 1.7 to 1."

The Parral system of agitation, like the Pachuca, is effected by the continuous transfer of the pulp from the bottom to the top of the tank by air-lift, but the details of the method of operation by the two systems are entirely different. In the Pachuca, which is fitted with a cone-bottom, the agitation of the pulp is effected by its continuous transfer from the bottom to the top of the tank, through a pipe 16 inches in diameter fixed centrally in the tank with its intake near the apex of the cone at the bottom and the delivery end at or near the top of the pulp charge. The compressed air is delivered to the intake end of the transfer pipe through a 1½-in. pipe capped at the end and perforated on the sides for a length of 6 to 8 in. back from the cap. To prevent the pulp from entering the perforations, a tight-fitting rubber sleeve is drawn over the end and clamped above the perforated section. When the compressed air is turned on, the rubber sleeve expands against the hydrostatic pressure surrounding it, and the air passes out under it and, entering and ascending through the transfer pipes, carries the pulp from the bottom and discharges it at the top of the tank. The mechanical defects which I found in the Pachuca tank and system of agitation will come under the following heads:

1. The tall narrow shape of the tank with its comparatively small holding capacity per pound of steel and its high cost of construction.

EXTRACTION-CURVES PLOTTED FROM RECORDS OF OPERATIONS IN PACHUCA AND PARRAL TANKS. SAMPLES TAKEN EVERY SIX HOURS AND ASSAYED.

2. The cost of elevating the charge to tall tanks during operation, barring plants erected on exceptionally steep millsites.

3. The imperfections of the means employed for admitting the compressed air to the lift-pipe, and excluding the pulp from choking the air-pipe during times when the air is shut off.

4. The excessive amount of power necessary to generate the high pressure and volume of air required to effect the agitation in a central lift-pipe of large diameter.

5. The imperfect mixture of the solid and liquid constituents of the pulp in the tank during agitation.

6. The difficulty of starting agitation when compressed air has been shut off and the solids in the pulp settled in the cone at the bottom of the tank.

In the Parral tank system these defects have been eliminated by the use of a plurality of transfer pipes of comparatively small diameter, the number of these pipes being in proportion to the diameter of the tank, which may be economically proportioned to its height so as to give the greatest holding capacity per pound of steel or material used in the construction. The accompanying illustration and table of comparison will indicate some of the advantageous features in construction of the Parral type of tank.

COMPARISON TABLE OF CORRESPONDING ITEMS IN STANDARD PARRAL AND PACHUCA TANKS

Points of Comparison.	Parral.	Pachuca.
Height in feet.....	15	45
Diameter in feet.....	25	15
Horizontal area in square feet.....	490.8	176.7
Effective holding height in feet.....	14	39
Holding capacity in cu. ft.....	7671.2	6891.3
Holding capacity in metric tons of solids:		
Pulp ratio: solution 2, solids 1.....	92.8	83.3
“ 1½ “ 1.....	139.4	125.3
“ 1 “ 1.....	155.3	139.5
Weight of steel plate and all construction:		
Material in pounds.....	14,650	33,000
Lb. steel per ton of 2.1 pulp.....	157	400
Lb. air-pressure required for agitation .8 to 10	30 to 50	

I have selected the dimensions 25 by 15 ft. as the standard size for the Parral tank for the following reasons:

1. A tank of these dimensions makes a convenient unit for most plants, as it holds from 90 to 100 metric tons of dry pulp of a specific gravity usually suitable in most ores for treatment.

2. The high holding capacity per pound of material in its construction.

3. Its comparatively low height, which makes charging possible by gravity flow in most hillside plants, and permits agitation by compressed air of 8 to 10 lb. pressure per square inch.

However, the system by which agitation is effected may be installed in and will work well in tanks of any diameter and any height. In the plant of the Veta Colorada M. & S. Co. the tanks were 25 ft. in diameter and the height was built up to 42 ft. to correspond with the Pachuca tanks included in the battery, as the walks on top and sampling platform could be more conveniently arranged in connection with a uniform height. All the trouble and expense due to the short life of the rubber sleeve as a nozzle on the compressed-air pipe and the high consumption of air required to operate it (the total hydrostatic pressure of the tank charge on this sleeve being 850 lb.) in the Pachuca tank is obviated by the air-nozzle ball-valve of the Parral tank. This valve is balanced in the hydrostatic head of the pulp charge except about 50 lb. due to the seat area. These valves have been in continuous operation for 16 months without renewals or showing any sign of loss of efficiency, so their life limit cannot be fixed. With these valves, agitation has been started and brought to normal running in 15 minutes after the air had been shut off and agitation suspended for 24 hours, by simply turning on the air.

The imperfect mixture of the pulp charge of the Pachuca tank due to the vertical settlement of the pulp immediately around the central transfer pipe, is prevented in the Parral system by creating a rotary flow in the tank charge whereby the whole mass revolves round and round from top to bottom within the tank, and the solids are thus carried spirally in suspension, and therefore the distance of their travel from top to bottom of tank is many times greater than if allowed to settle vertically. The rotary flow is created by the force of the horizontal discharge from the several transfer pipes in the same direction with respect to the side of the tank on the surface of the charge.

The surprising facts in connection with the rotary flow in the tanks are that it is generated by so small a force

COMMENCEMENT OF PULP TRANSFER IN PARRAL TANK.

as the spouting from the discharge of the transfer pipes and that when generated on the surface of the charge it will extend to the bottom of the tank with sufficient activity to prevent the settlement of the pulp in dead accumulations on the bottom such as takes place in tanks 42 ft. high. An analogy, showing the mobility of water under slight force and the persistence of flow when once created in it, is seen in the great ocean currents which, generated by the trade winds, revolve continuously between the shores of continents thousands of miles apart. The Gulf stream is generated by the easterly trade winds blowing on the surface of the Caribbean sea which drive these waters westward before them till they make their escape back again into the Atlantic ocean between Florida and Cuba, where, as is generally known, the flow of the current is 6 ft. per second and its strength such as to sweep the sea-bottom, here 600 ft. below the surface, as clean as a floor and force the current in a rotary path across the Atlantic ocean to Europe and back again. Whether this analogy is correct or not, the fact remains that the rotary flow created at the surface of the charge in a Parral tank maintains a continuous revolution in the entire mass

within the tank which keeps the solid and solution constituents of the pulp in proper proportional mixture, in every part of the tank at all times during treatment, while the spouting of the pulp at the surface of the charge gives the aeration required for the chemical reactions.

*Extraction.*—That the extraction is better in the Parral tank as compared with the Pachuca is shown by the diagram on p. 42, which is self-explanatory. The data from which the curves are traced were taken from the log records of the results obtained when both tank systems were being operated by the individual process.

*Chemical Constituents of Solution:*

KCN .....	15%
Protective alkalinity .....	850 gm.
Lead .....	3 gm.

*Physical Condition of Pulp:*

Dilution .....	2 to 1
Specific gravity .....	1.26
Screen sizes: +200, 15 to 20%; -200, 75 to 80%.	

*Extraction:*

Prior to tank treatment, 10 to 20%.

By tank treatment, as per chart.

Total extraction, as per chart +10 to 20%.

In explanation of the percentage column of the above chart, it may be said that more than 62% of the metal was extracted during the first six hours' agitation.

The low extraction shown in the curves was due to the character of the dump ores being treated. The dump as it was built up was mixed with accumulation of rotten timbers from the mine workings and the ashes and charcoal from the steam plant near the shaft. It contained, besides, the mud and oxidized matter from the ore-washer which was on the dump and used for washing the mine ore preparatory to hand sorting.

*The Kelly Filters.*—These did satisfactory work on the slime, which was very clayey. The filter test made on the slime of an average sample of the ore before the filters were ordered, showed that under 40 lb. air-pressure it was only possible to build a cake  $\frac{3}{8}$  in. thick in 20 minutes. In regular operation, after the presses were erected, there was no difficulty experienced in building a cake 1 in. thick in the same time and drying it to 15% moisture under 30 lb. air-pressure for 3 minutes. Had water not been available for flushing the discharged cake to the dump, it would have been dry enough at 15% moisture for disposal by belt-conveyor. Having filter capacity to spare, one of the filter-presses was very successfully used as a clarifier for the decanted solution from the Dorr thickening tanks on its way to the zinc-boxes for precipitation. This solution flowed through the leaves of the press by gravity under a head of 25 ft. and came out perfectly clear. About a  $\frac{1}{4}$ -in. cake built up of the fine matter suspended in the solution would deposit on the leaves each 24 hours. This had to be discharged, as nearly all flow stopped when a  $\frac{3}{8}$ -in. cake would form on the leaves.

## Dividends

The Colorado M. Co. paid a dividend of 3c. per share on June 25.

The Daly West has declared a dividend of 30c. per share, payable July 10. This makes a total paid to date of \$6,552,000.

The Bunker Hill & Sullivan M. & C. Co. paid dividend No. 178 of \$65,400 on July 3. This makes the total amount of dividends paid \$13,584,750.

The Wettlaufer Mining Co. has declared a quarterly dividend of  $2\frac{1}{2}\%$ , with an extra dividend of  $2\frac{1}{2}\%$ , payable July 20. This brings the total dividend disbursement to 30% of the capital.

The Colorado Fuel & Iron Co. has declared a dividend of  $2\frac{1}{2}\%$  on its preferred stock. This is the first dividend paid since 1908 on the preferred shares, on which 8% per annum is guaranteed.

## Mining in France

PARIS CORRESPONDENCE

A statement has been issued by M. Péchadre, who was delegated by the budget committee of the French Chamber to draw up a report respecting French public works. The chapter devoted to mining wealth contains a good deal of interesting information concerning the present mining situation in France. He describes the mining industry as one of the most prosperous of the nation. There are 1483 concessions covering an area of 1,200,000 hectares (one hectare equals 2.471 acres), all which concessions, it is said, are being actively exploited.

The annual output of the minerals in France is estimated at 945,000,000 francs value. This includes quarries, but does not refer to Algeria, which is included in many statements, at times leading to confusion in respect to France proper. The number of workmen engaged in mining is 350,000.

The number of coal and lignite concessions is 641, of which 298 are being exploited. The principal centres for the production of coal are the well known Nord and Pas de Calais, which furnish between them about 67% of the total coal production of France. There are other coal centres of local importance, such as the Loire, the Gard, Saône-et-Loire, L'Aveyron et le Tarn, and finally there are the Bouches-du-Rhône and the Puy-de-Dôme et l'Allier. The production of coal in France is increasing. Nevertheless, the country is unable or is not equipped to produce the quantity necessary for its consumption, and it is obliged to import coal from England and sometimes from Germany and Belgium; to the latter countries it returns the compliment by exporting fuel to districts convenient to its source of supply.

Of the ironfields of France the principal centres are the Meurthe-et-Moselle, where over 50 mines are worked. Then follow Normandy and Anjou, where considerable iron deposits have been discovered; and, finally, in the Pyrenees high-grade iron ore is produced and is used for special purposes. It may be mentioned in connection with the Normandy deposits that the Germans realize their importance and have established large plants there to supply the lack of iron ore in Germany, and when these are well advanced France will become a large exporter of iron ore. As to other minerals, except gold and one or two others, the situation is not so satisfactory. France has some 90 mines of various minerals such as iron pyrite, manganese, antimony, copper, lead, zinc, and silver, which produce a value of about 20,000,000 francs of mineral of various kinds. Most of them yield but small profits, except the zinc and iron pyrite, which, on the contrary, have paid well.

Gold-mining is improving. A number of companies were formed with success at Lucette (Mayenne), Bellière (Maine-et-Loire), and Chatelet (Creuse). Encouraged by the results, many prospectors continued the search in districts such as Aurieras and St. Sulpice-Laurière, where numerous veins have been discovered, and concessions are being applied for from the Ministry of Public Works. There are 41 concessions for salt mines and brine wells, where about 250,000 tons of refined salt, 115,000 tons of crude salt, and 490,000 tons of salt in solution is produced, the last named for the production of soda.

There are now 190 applications before the Ministry of Public Works for mining concessions. 20 of which are for coal, 70 for iron, 38 for gold, 20 for salt, and 42 sundries. The statement appears at a time when the mining laws of France require revision; in favor of the miner on the one hand, while the Government appears desirous of getting more revenue out of them, on the other. While the matter of revision remains unsettled, little may be said; but enough is known outside the report to confirm a *couleur de rose* view of the coal and iron situation, particularly of the latter, in the east near the German frontier and in the north in Normandy; the revival of the gold industry also promises well.

## Churn-Drilling in Shaft-Sinking

By TOM MCCORMAC

Churn-drilling has long been practised, and is a most common method of drilling any soft rock, particularly in surface work. In these latter days of the almost universal use of compressed air and machines for drilling purposes, churn-drilling has not been used with the frequency that is justified by the results which can be obtained from its use. In hard rock the method cannot compete with the power-driven drill, but in shaft work most excellent results have been obtained in the softer rocks. Chief among the advantages of churn-drilling is the fact that in any ordinary shaft drilling can be started within ten minutes after the broken rock from the previous round has been cleaned up. The hole drilled, furthermore, is large, and, when loaded, the powder lies well toward the bottom, where it can do the best work. And not least of the advantages of the drill is the fact that anyone can operate it.

In sinking through any soft rock the churn-drill will compare most favorably with the air-driven piston drill. In speed of drilling it is even the faster in some cases, since no time is consumed in the unproductive work of 'setting up' and 'tearing down.' It has the further advantage of requiring no expense for power. While no particular skill is required in its operation, still the hard work involved in its use makes a careful selection of the drilling crew imperative. A good active workman will accomplish twice as much drilling as will a man only a little less energetic; while in the hands of poor men, churn-drilling would probably fail entirely. Churn-drills may be had in a great variety, ranging from the elaborate outfit used in testing placer ground to the simple bar of steel sharpened at each end.

I am indebted to W. H. Storms<sup>1</sup> for several of the ideas which I used successfully in sinking a two-compartment shaft through a firm but soft shale; but I was first induced to try the drills by Martin Empey, an able miner at Ely, Nevada. In this shaft it was the usual routine for four men to drill 10 holes from four to five feet deep, and blast in four hours. No piston drill could compete with the churn-drill in this class of rock. I used the common 7/8-in. drill steel sharpened on each end and in 7 and 9-ft. lengths. Should deeper holes be desired, I would advise the purchase of bits fitted for 1-in. pipe and which can be obtained from any dealer in mining machinery; these can be attached to pipe of any convenient length. The shape of the bit is of more importance than in hand drilling, and it should be carefully made, rather strongly forged, exactly gauged, and tempered very low. A churn-drill is not intended for hard rock, and a low temper—almost a blue—will give the best results.

Usually a hole was started with a hammer and drill, although there were times when the rock was soft enough to auger a short distance, and at other times an old 'gun' or 'bootleg' would be cleared out and made to serve as a short hole in which to start churning. Until a hole reaches a depth of a foot or 18 in., the drilling goes rather slowly; after that it goes surprisingly fast. Up to a depth of three feet the hole can be cleaned if necessary with an ordinary machine 'spoon', but a deeper hole can be more quickly cleaned with the device described by Mr. Storms—a bar of 3/8-in. iron with an eye welded in the end through which can be drawn an old rope yarn or a piece of rag. This, dropped into the bottom of the hole, is withdrawn and wrung out, and the operation repeated until the hole is dry. Should there be too much water, it can be removed by using a piece of 1/4-in. pipe bent over at the top and using one hand at the top for the valve, or it can be removed by using the sand-pump. A simple form of the latter is a pipe having the bottom drawn to a small opening which is closed with a steel ball, held from being thrown out of the pipe by a pin a short distance above. Plenty of old sacks for 'mop rags' are

needed, and a couple of tin cans, without bottoms, will occasionally be found useful for easing the top of a large hole.

One of the most frequent causes of trouble in drilling with the churn-drill is the encountering of caving or raveling ground. In such case the supply of drilling water must be kept as low as possible, in the hope that the thick mud will plaster the sides of the holes. If a drill should break, it can usually be loosened in the hole and fished out with the scraper, or it can sometimes be made to adhere to a chunk of mud or clay on the end of the loading stick or scraper. The bar magnet, suggested for this work, would, I am afraid, prove to be far too interesting a plaything to be permitted in a shaft.

## Copper Producers' Association Report

The Copper Producers' Association statement, July 8, shows a decrease during the preceding month in accumulation in this country of 5,280,639 lb. The details are as follows:

	Pounds.
Stock of marketable copper of all kinds on hand at all points in the United States, June 1, 1912	49,615,643
Production of marketable copper in the United States from all domestic and foreign sources during June .....	122,315,240
Deliveries for consumption, June.....	66,146,229
Deliveries for export, June.....	61,449,650
Stock of marketable copper of all kinds on hand and at all points in the United States, July 1.	44,335,004
The changes in surplus since July 1, 1911, have been as follows, in pounds.	
	Increase.                      Decrease.
July, 1911 .....	19,695,306
August .....	4,297,357
September .....	7,453,355
October .....	5,897,214
November .....	23,212,454
December .....	22,330,493
January, 1912 .....	22,173,252
February .....	3,301,944
March .....	572,431
April .....	2,927,829
May .....	15,450,386
June .....	5,280,639

GYPSUM mined in 1911 amounted to 2,323,970 short tons, valued at \$6,462,035, as stated by E. F. Burchard in an advance chapter on gypsum from 'Mineral Resources for 1911,' published by the U. S. Geological Survey. This was a slight decrease from the figures for 1910—1.05% in production and 0.94% in value—but while the industry was not especially active, certain changes, such as the replacement of old mills by a smaller number of larger modern mills and the establishment of mixing plants in commercial centres, should result, according to Mr. Burchard, in the saving of freight charges on finished plasters and enable the products to be sold to the consumer at low rates. Gypsum was produced in 17 states and in Alaska from 78 mills. The imports for 1911 were considerably reduced.

MINERAL deposits of importance in Turkey are those of emery, chromite, copper, and marble. Great supplies of marble in matchless varieties of color are found on the coast of the Sea of Marmora and elsewhere, most of them unworked. Eski Shehr practically supplies the entire world with meerschaum. The work of mining is still pursued in the most primitive fashion with picks and knives. The output goes almost entirely to Vienna, the average annual value being about \$300,000. Why American dealers should buy meerschaum in Vienna instead of at the production point is not apparent. Turkey has many hot and mineral springs, the most famous being those at Brusa and Tiberias, which only await foreign capital to gain renown among the health resorts of the world.

# El Porvenir Mine in the District of Mallama

By F. P. GAMBA

In almost all the mines in the southern part of Colombia the ore is genetically related to volcanic action. In the case of the El Porvenir mine, it is connected with the most important volcano ever existing in South Colombia, the Gualcala. This volcano, at present extinct, was active until a recent geological epoch. The last lava flow from Gualcala was an augite andesite, which I have called propylite in my Spanish writings on the subject. Afterward the volcano ejected only breccia and mud. To this breccia I ascribe the origin of the ore deposits, and for that reason I call such material madre (mother of the

## SITUATION AND GENERAL RELATIONS

El Porvenir mine is one of a group of concessions owned by a native company named Compañía Minera de Mallama, and it is the only one which has been much explored. The group consists of 30 pertenencias of 600 by 240 metres each. El Porvenir is near the peak Gualcalá and beside the crater on the west or Pacific slope of the cordillera which trends north-south.

It is a noteworthy fact that all the big craters here open to the west, and therefore the most important outflow of lava was in that direction.

The altitude of the workings is 3400 metres (11,100 ft.); mean temperature, 7°C.; the climate very healthful.

The distance to Guabo, a village on the highroad to Barbacoas, is three and a half kilometres. The distance from Guabo to Barbacoas is 110 km., a three-days journey on muleback. Barbacoas is the river post on the Patia river, and is one day's steamer travel from Tumaco, the seaport. The distance to Tuquerres, the local centre for provisions, is 50 km. Excellent native labor is available, the peons making good miners and millmen. The wages, reduced to American currency, are as follows: Peons, 16 to 20c., with board costing 26c.; carpenters and blacksmiths, 66c., with board costing 36c.; millmen, monthly, \$9.60, with board at the same rate as the carpenters. The miners prefer contract work. They are hard workers, intelligent, and particularly courageous. When contracting they earn an average of 60c., and then demand the same board as the millmen.

Timber for underground use is cheap—\$1.60<sup>1</sup> per cubic metre; squared or sawn timber costs \$32 for the same measure. The explosive employed here, and in almost all the mining enterprises in southern Colombia, is 'rackarock.' Its advantages in transportation, freedom from import duty, make it preferable in a country like this. The cost of freight is: Tumaco to Barbacoas, 40c. per *bulto*<sup>2</sup>; Barbacoas to Guabo, \$1.60 per *bulto*; Guabo to Porvenir, 32c. per *bulto*. For heavy pieces the cost is very high. The currency is silver at 250% exchange rate against United States currency.

## ORE DEPOSITS

The ore is found along the contact between two eruptives; monzonite (locally called *granito*) and propylite (an amphibole augite andesite called *peña verde*). The ore is not confined to one of the two eruptives, but extends into both rocks. The monzonite (with all the transitions from true syenite to granite) forms the basement of the metaliferous belt that runs south for more than 150 km. along the western slope of the cordillera. It appears in all the mines of the mining districts of Mallama and Samaniego. The propylite is an eruptive characteristic of the Gualcala zone and peculiar to the mining district of Mallama. Covering the monzonite and propylite is a thick bed of volcanic breccia formed by cemented fragments of propylite and on this are layers of tuff. The ore deposit is in a system of east-west parallel veins and veinlets, which at the same time is more or less parallel with the line of contact, having, therefore, some stringers in the propylite which lies south of the contact, and others in the monzonite which lies north of the contact. Occasionally, as the veins pass from one rock into the other, they are on the contact itself. Some of the stringers or narrow veins are very irregular in strike, and form lenticular masses deposited in the joint planes. Outside of this, as the rocks are broken by cleavage into parallelopipeds, all fine cracks have been penetrated by the solutions, and the rock itself, principally the monzonite, has been impregnated and metasomatically replaced by ore. The individual lenses of ore are from 0.10 to 1.60 m. thick and very

MAP OF COLOMBIA.

formation). During its last convulsions, the Gualcala vomited only tuff.

My experience in the mines of this territory permits the following general conclusions:

- (a) The metalliferous deposits of the region had a common origin.
- (b) The ore-bearing formation is the breccia ejected from the volcanoes.

The mineral-carrying waters of these muddy eruptions percolated through the mass of the breccia to impregnate the subjacent rock, filling at the same time the crevices, fissures, joint places, and cleavage cracks, so as to form the *mantos*, stringers, and networks of ore characteristic of the mineral formation here.

- (c) The actual orebodies have been formed by reconcentration under the influence of surface waters.

El Porvenir mine is one of the most appropriate, in which to study the genesis of the deposits which characterize the Narino department, and for this reason I have selected it for a brief description, in which to summarize the principal features of the petrology (and economic conditions) of the locality.

<sup>1</sup>All values reduced to U. S. currency.

<sup>2</sup>The *bulto* (bundle) weighs 100 to 130 pounds.

variable. They are separated by layers of metamorphosed country rock, averaging a half metre in thickness. The lode is known to be nearly 100 m. thick and is exposed by superficial cuts for 1200 metres.

The main fault runs north-south, cutting the lode, and at the intersection is an open pit connected with underground workings. The inspection of the walls in the open-cut shows clearly the manner in which the orebody was formed by the descending waters that percolated through the bed of breccia. At the same time, all stages of the process of metamorphism of the country rock into ore may be seen.

The most abundant mineral, and the last to be deposited, is mispickel. It is followed in order of quantitative importance by pyrite, blende, chalcopyrite, and galena. The accessory minerals are tellurides (whose existence is known by the  $H_2SO_4$  reaction), sulphides of silver, native silver, and gold.

In the gangue may be distinguished stringers of quartz, solid sulphides, and altered country rock.

The ore contains some free gold, too fine to be distinguished with the magnifier. All the minerals mentioned are accompanied by gold and silver, but the richest ore is pyrite. The average value of the ore is nearly \$30; for the pyrite it is \$150 to \$238. The altered country rock assays \$9 per ton.

The workable ores can be classified as follows: (a) sulphides, 5% of the whole, with an average value of \$200; (b) quartz and metamorphosed rock, 10% of the whole, with value of \$20; (c) impregnated rock and saprolite, 85% of the whole and value of \$9. The ratio of the gold to silver by weight is 1:6.

At present El Porvenir mine is only a promising prospect. Early this year a 3-stamp Krupp mill was erected, the stamps weighing 550 lb. They drop  $7\frac{1}{2}$  in., 75 times per minute. Though the ore generally shows no colors in the pan, it pays well in the mill. The plates are 1 by 3 m. in size. The capacity of the mill is from 4 to 5 metric tons per day. When running on rich ore and pyrite the yield of amalgam is 400 to 1000 gm. per 24 hours. From the poorest ore the yield is 40 to 80 gm. The amalgam, by reason of the climate, is hard. It must be cleaned carefully with hot water, for it encloses large quantities of sulphides; its product in bullion is 22% of 700 fineness. The mill is driven by a 18-in. Pelton motor with 40-m. head and water consumption of 7 litres per second. Below the plates is a mercury trap, followed by two wooden spitzkasten. The rich sand is carefully collected for future treatment. The slime is run to the creek.

The additional plant now in erection included a common reverberatory furnace for dead roasting, with capacity of 2 metric tons per 24 hours, and a cyanide plant for percolation treatment of the roasted material. All of this equipment is home-made of wood. My experience with the roasted sand is that a recovery of 95% can be made in 36 hours. The plant is erected practically at the mine to avoid the transportation of the ore which, in a country like Colombia, is the most difficult and expensive part of mining. The ore, from the open-cut, costs in the mill, all expenses included, \$0.30 per metric ton. The milling adds \$0.68. From underground the ore costs \$2.50 per ton delivered in the mill. As a rule the sulphides are sorted out by hand and carried to special dumps to be treated afterward or shipped to the establishment of the Gualcala Mines Co., which is near by. If the road to Barbacoas was made suitable for freight wagons the rich pyrite could be shipped to the United States at good profit; unfortunately the freight cost at present is prohibitive.

Worked as a low-grade mine El Porvenir could be made a big producer. The financial condition of the owners oblige them to work on small scale, practising coarse concentration and throwing into the waste all ore lower than \$10 in value. Practically 85% of the whole is not now treated. Similar conditions exist in the case of many mines in the vicinity where the same kind of concentration is practised. An enormous amount is thrown away, but the owners obtain nice profits.

In the course of the next six months the present plant will be enlarged to 9 stamps, ordering two batteries more from the same maker; the Krupp machinery has given the highest satisfaction, the design being such as to make it easily transported, and the erection of the steel frame being rapid and easy. The development of the mining industry in this part of the Republic will be slow if things continue as they are at present. Few people, and those with only limited capital, are interested in mining. To put things all right, and to bring the country up industrially to the level warranted by its mineral resources, it is of the utmost importance that people and capital come into the country from outside.

The only large foreign mining concern existing at present here is the Gualcala Mines Co., an American enterprise. This company owns a great area of mineral land and has just erected a modern cyanidation plant in this same mining district. The ore is similar to those described, but the orebodies are quite different. They take the form of fissure veins rather than that of an impregnation as is the case of the El Porvenir mine.

## Gold Deposits of Gibbonsville, Idaho

By FRANCIS CHURCH LINCOLN

Gibbonsville is situated on Dahlenega creek, just above its junction with the North Fork of the Salmon river, in Lemhi county, Idaho. Until recently the nearest railroad point was Divide, Montana, 86 miles distant on the Oregon Short Line, and all freight and mail came from there by way of Wisdom in the Big Hole basin, and thence across the continental divide into Idaho. The new Pittsburg & Gilmore railroad now has a terminus at Salmon, Idaho, 36 miles from Gibbonsville, and mail comes by this shorter route, although, on account of excessive freight rates, some freight still comes by way of Divide and Wisdom. The Gibbonsville region, comprised in the Dahlenega mining district, has produced a large quantity of gold from both placers and lodes, but unfortunately only fragmentary records of its history and production are available. The property upon which the greatest amount of work has been done is that of the American Development, Mining & Reduction Co. This ground is credited with a production of \$1,500,000. The mine has changed hands several times, spent five years in the hands of a receiver, and lost a 30-stamp chlorination mill by fire. It is now equipped with a new 30-stamp cyanide plant, and, although work is at present suspended, timber has been ordered for a new 500-ft. shaft, so its activities may be expected to commence this summer.

Several other mines in the district have made notable productions. Among these may be mentioned the Clara Morris group belonging to the Large estate of Butte, and the McCarthy, both north of the A. D. M. & R. mine; the Corn Beef group, belonging to the O'Rourke estate of Butte, and the Anderson group, to the west; and the Twin Brother group belonging to Henry Seligman, of New York, to the south. Not one of these properties, however, has approached the production of the A. D. M. & R. They have all been lying idle for a number of years, but the coming of the railroad to Salmon has stimulated mining in Lemhi county, and this stimulation has begun to be felt at Gibbonsville. As a result, O. P. Zortman secured a lease on the Twin Brother group last summer and began to develop that property; Messrs. Edwards and Roberts purchased the Anderson group; work has commenced on the McCarthy; and the Butte claim-holders are considering the further development of their properties. No placer properties are in operation at present. Guy Stapleton, of Butte, has many of these under option, and last summer made an unsuccessful attempt to drill the North Fork.

The hills in the vicinity of Gibbonsville are well wooded with spruce and yellow pine, and ranching is profitable wherever the creek bottoms attain sufficient width. The altitude of the town is 5400 ft. by aneroid barometer. From the creek bottoms the hills rise steeply for about a thousand

feet. To the northward, the mountains of the continental divide make a great semi-circular sweep with an eight-mile radius about Gibbonsville as a centre, and across the divide lies Montana. At Gibbonsville, Dahlenega creek flowing west is augmented by Anderson creek flowing south, and turns southward, entering the North Fork of the Salmon river just below the Twin Brother group at the southern end of the mineral district.

The principal country rock is slate. This has been briefly described by W. H. Weed.<sup>1</sup> The slate includes quartzose, feldspathic, and micaceous facies, and its structure varies from thinly to thickly laminated. The strata have a general north-south strike, and dip steeply to the east. No fossils were observed. The beds are probably of Algonkian age, and possibly referable to the Prichard slate of the Coeur d'Alene, in which the gold veins of that district occur.<sup>2</sup> The only other sedimentary rock in the region is a quartzite over a hundred feet in thickness which is exposed on the west side of Dahlenega creek in the northern part of the district, and has been taken up by Mr. Hughes as a lode claim. This quartzite is interesting because it contains gold. I obtained an assay of 40c. per ton in gold and was credibly informed that assays of \$1, \$2, and in one instance even as high as \$8, had been obtained by disinterested parties. As there are no marked signs of secondary mineralization, the quartzite may represent an ancient placer.

At one point in the high placer west of Anderson creek, a small patch of decomposed granitic rock outcrops in the slate. It is an eroded knob of earlier age than the slate, and probably is Archean granite. A great dike of basic rock extends down Anderson creek to its junction with Dahlenega creek and then follows Dahlenega creek to its junction with the North Fork, down which it extends for an undetermined distance. This dike is narrow on upper Anderson creek, widening gradually to a thousand feet at Gibbonsville. The rock of which it is composed consists of large white crystals of feldspar with a dark background of ferromagnesian minerals free from olivine. Another dike of gabbro occurs west of the North Fork near its junction with Dahlenega creek, and a third dike of like character forms the crest of the continental divide on the trail from May creek, Montana, to Gibbonsville. These dikes appear to be similar to the diabase dikes and sills of the upper St. Joe river basin, south of the Coeur d'Alene district,<sup>3</sup> and may be approximately contemporaneous with them. Several small pegmatite dikes were observed in the gabbro where exposed in the bedrock of the Anderson creek high placer.

Numerous north-south faults occur. Within the slate these are marked by narrow clay seams and have caused but slight displacements, but at the slate-gabbro contact east of Anderson creek there is a brecciated fault-plane which indicates a much greater movement, and the Twin Brother adit disposes not only this contact fault, but also a number of parallel, brecciated fault-planes within the basic dike. These facts taken in conjunction with the occurrence of granite and quartzite on the west side of the Anderson creek dike only, point to a very considerable up-throw of the major portion of the dike and of the region to the west of it.

The Gibbonsville gold ore occurs in fissure veins in the slate. These veins are said, on good authority, to extend into the gabbro in some instances, and fissure veins which probably belong to the same system certainly do occur in the Anderson creek dike, but as yet no ore has been mined from veins in the igneous rock. The ore-bearing veins were probably formed by hot ascending waters circulating in fissures produced subsequent to the consolidation of the gabbro. It is possible that the gold was derived by the leaching of the auriferous quartzite previously described. The productive belt in the neighborhood of Gibbonsville has a length of about two miles in a general north-south direction, and a width of about half a mile. The veins

within this belt all appear to belong to the same system. They have a general east-west strike, cutting across the stratification of the slate. Their dips are steep, and in all cases save one are toward the north. They are narrow but fairly persistent, and in some instances can be traced for the length of several claims. Post-mineral faulting on a small scale is extremely prevalent. The faults are generally pivotal in character. The greatest displacement observed was 25 ft. The ore-shoots vary in width from a few inches to a few feet, and are rarely over 2 ft. wide, although in one instance a width of 12 ft. is said to have been attained. They are frequently several hundred feet in drift length. The barren intervals between shoots are of variable length. So far as known, all the ore-shoots pitch toward the east, the direction of the dip of the slate.

The ore in the narrow fissure veins of Gibbonsville is high grade, ranging in value from \$20 to \$200 per ton. Some rich ore occurred in the shallow oxidized zone. The gold was free there, but the sulphide ore below is base. The principal ore minerals are quartz, auriferous pyrite, and chalcopyrite. The vein filling varies from nearly solid pyrite with a slight admixture of quartz and chalcopyrite to almost solid quartz with a few scattered cubes of pyrite and specks of chalcopyrite. East of the Anderson creek dike the copper content rarely exceeds 0.5%, but west of the dike it is much higher. Examination with the naked eye shows that the pyrite retains its own crystal outlines when imbedded in the quartz, and that the quartz keeps its shape when in chalcopyrite, but that the chalcopyrite only shows crystal faces when it occurs on the interior of vugs. The order of formation was therefore (1) pyrite, (2) quartz, and (3) chalcopyrite.

These later-formed particles of chalcopyrite may be the result of secondary concentration by cold descending waters. In this case, the percentage of copper is the measure of secondary concentration, and, if the erosion has not been too rapid, also proportional to the amount of erosion. Thus the high copper content of the veins west of Anderson creek is explicable on the ground that there has been a greater amount of erosion in that locality. This conclusion is borne out by the structure, which has been shown to indicate an up-throw of that section. A slight secondary silver enrichment in the upper portions of the orebodies is suggested by the fact that in 1896 MacDonald<sup>4</sup> reported 99% gold and 1% silver by value in the ore, while last summer my assays of samples which probably came from greater depths than MacDonald's, showed only traces of silver. Native gold has been occasionally observed in small specks in the oxide ore, but in the sulphide ore the gold occurs disseminated in the pyrites. The iron pyrite is rich, the copper pyrite is poor, and the quartz practically barren. The relative gold content of these minerals is shown by the following assays of fairly pure material selected from a single sample.

Mineral.	Oz. Gold per Ton.
Pyrite .....	2.68
Chalcopyrite .....	0.18
Quartz .....	0.01

Placer deposits occur in both terrace and creek gravels. One terrace occurs west of Anderson creek near its junction with Dahlenega, and another west of North Fork near its junction with Dahlenega creek. These terraces were formed by the present streams at an earlier stage in their history. The placer gold is very pure, having a value of \$18 per ounce. It is nearly all coarse, small nuggets of from \$3 to \$10 being common<sup>5</sup>, and occurs in worn particles which are usually free from quartz. It is evident that this gold cannot have been derived from the local lodes, since particles of the lode gold are fine, while particles of the placer gold are not only coarse, but also show by their abraded surfaces that they have come from a distance. Placer gold of the same character is found across the continental divide in Montana on Hughes creek, a tributary of the Bitter Root river and on May and Pioneer creeks, branches of Trail creek, a tributary of the

Big Hole river. The placer gold in all these localities appears to have been derived by reconcentration from an ancient river bed, probably of Neocene age.

The conditions are, on the whole, favorable to mining. Owing to lower elevation, the climate is much less rigorous than that of the adjoining parts of Montana. The slate drills and breaks easily. Little timbering is required, and when supports are necessary, a good quality of timber can be obtained within the district. There are a number of small water-powers which can be developed at small cost. One of these is now being used by the A. D. M. & R. mine to run its air-compressor, and another to run its mill. The only adverse conditions are the narrowness of the veins and the high freight rates. The usual method of mining is to strip the hanging wall of a vein and bar down the ore.

In the early days of the camp the free-milling surface ores were treated by amalgamation in arrastres and stamp-mills. As the ores became more basic it was found necessary to employ chlorination, and MacDonald has described the plant erected by the A. D. M. & R. company for this purpose. That mill was burned and the new one erected by the same company employs cyanidation. The ore is crushed by stamps through 45-mesh screen and the free gold removed by amalgamation on plates. The pulp is then concentrated and the concentrate cyanided. A series of tests that I made showed that there is no free gold in the deeper ores, and that in order to obtain an extraction of 90% by cyanidation it will be necessary to slime them.

## Regeneration of Cyanide Solution

By W. D. WILLIAMSON

In 1899 while treating cupriferous tailing in North Queensland, the excessive cyanide consumption, due to the presence of copper carbonates, made profitable treatment exceedingly difficult. Solutions rapidly fouled, precipitation was very unsatisfactory, and extraction decreased until the only alternative was to discard the fouled solution and make up fresh solution. Changes of solution were very frequent and involved considerable expense and loss of time. This trouble was finally overcome by preliminary leaching with sulphuric acid, about 12 lb. of acid being used per ton of tailing treated. Later, when sulphide ore had to be treated, sulphuric acid leaching was useless.

Experiments made on solutions, which had become charged with copper, demonstrated the fact that a very considerable saving of the combined cyanide could be effected by the addition of sulphuric acid to the solution, in sufficient quantity to precipitate all the copper as  $\text{Cu}_2(\text{CN})_2$ —namely:

The insoluble  $\text{Cu}_2(\text{CN})_2$  was separated by filtration, and the clear filtrate containing the HCN neutralized with a slight excess of alkali.

The experiments were sufficiently encouraging to induce me to continue the method on a working scale. As solutions became overcharged with dissolved copper, sulphuric acid was added to the sumps in sufficient quantity to complete the above reaction. The precipitated  $\text{Cu}_2(\text{CN})_2$  was settled, and the clear supernatant liquor was drawn off and neutralized in a separate sump, and was then used as a fresh clean cyanide solution. The settled  $\text{Cu}_2(\text{CN})_2$  was collected and saved for shipment to smelter. The possible recovery of the cyanogen in combination with the copper as  $\text{Cu}_2(\text{CN})_2$  still gave me material for experiment.

Heating with acid I consider impracticable, as it would involve distillation of the liberated HCN, and probably excessive loss of cyanogen, owing to the decomposition of the cyanogen radical in the presence of heat and strong mineral acids. Eventually I found that an almost complete recovery of the cyanogen in  $\text{Cu}_2(\text{CN})_2$  could be obtained by suspending the  $\text{Cu}_2(\text{CN})_2$  in water, and passing

sulphuretted hydrogen when the following reaction takes place:

The insoluble  $\text{Cu}_2\text{S}$  was separated by filtration and the clear filtrate containing the HCN neutralized with alkali.

Finally, I combined the two operations by adding to the cupriferous cyanide solution sufficient  $\text{Na}_2\text{S}$ , to precipitate all the copper present, afterward adding the requisite amount of sulphuric acid to complete the following reaction:

The precipitated  $\text{Cu}_2\text{S}$  carries down with it the precious metals contained in the solution and is collected, dried, and shipped to smelter. The clear liquor is decanted or filtered, and sufficient alkali added to combine with the free HCN liberated by the previous treatment.

This process, which theoretically should recover all the cyanogen in combination in cupriferous cyanide solutions, has never been used to my knowledge on a working scale, but in laboratory experiments as high as 90% of the combined cyanogen has been regenerated and made available as a clean copper-free cyanide solution.

Commenting on this method, Andrew F. Crosse said: "Some years ago I was engaged in investigations in the cyanide treatment of cupriferous ore near Pilgrim's Rest. During my experiments I found that the solutions were always highly charged with copper, and I was unaware that anyone else had the idea of treating cupriferous cyanide solutions with sulphuric acid. I made many experiments. It was difficult at first to find out exactly the right amount of acid required. Then I made a long series of experiments to find out how much gold and how much silver was precipitated. I never obtained 100% of gold by precipitation; I used to get, if I remember rightly, 88 to 97%. I think that nearly all the silver was precipitated, but not quite all the copper. It was a very nice precipitate to handle; it would settle very easily. I treated over a ton of solution in this way. I then regenerated the hydrocyanic acid solution, after decantation, by means of caustic soda.

"The second part of Mr. Williamson's paper is certainly an improvement on what I did. I simply took the precipitate, dried it, calcined it, and melted it, and I got a little bar containing about 95% of copper, 1% of gold, and 2% of silver; but I certainly think that where sulphuric acid can be obtained fairly cheaply, and where a certain amount of cyanide is decomposed by copper in the ore, the method is worth considering. Supposing some gold does remain in solution, the solution is simply passed through the zinc-box after regenerating with caustic soda.—*Journal Chem., Met. & Min. Soc. of South Africa.*

THE high and increasing prices of tin during recent years has naturally led to attempts to find and open up new tin districts, particularly in the United States and in British Africa. But the totals contributed by these new sources are hardly yet appreciable; the production in Nigeria, for example, in the first four months of this year probably did not reach 350 tons of metal—quite an encouraging output, of course, but not calculated to affect the price on the London market. The American production so far has been negligible. For all practical purposes the world's supply of tin is still provided by a very few older localities. It is remarkable, indeed, how few and circumscribed these areas are; a southern province of China, the Straits Settlements, two small Dutch islands in the Malay Archipelago, the eastern coast of Australia, Tasmania, Bolivia, and Cornwall—these were all, though now there must be added South Africa, which last year provided about 2000 tons.

THE New Chucuitambo Gold Mines, near Cerro de Pasco, Peru, produced 29 kg. of gold during March, and it is expected that the cyanide plant will soon further increase the production.

# Dry Concentration of Placer Gold

By F. J. H. MERRILL

The recovery of gold by dry concentration from placer gravel, and from various ores, is a subject which has received much attention in arid regions, where water is too scarce or too expensive to be used in the ordinary processes. Inventive minds have for years been occupied with dry concentration in all its phases, and many machines have been devised to separate the precious metal from the associated rock fragments. Several have been built which effect a satisfactory separation on trial runs with selected material, but comparatively few have been made which, in continuous use, give good results on material varying in coarseness and in gold content, and some machines, otherwise good, are lacking in durability.

The fundamental principle of concentration, with either air or water, is to partly overcome gravity in the particles under treatment by an upward flow of the fluid used, and, through what is known as 'hindered settling,' to effect a classification of the fragments by the differences in their specific gravities and thus facilitate the separation of the gold from the valueless material mingled with it. The physical differences between air and water render their action in concentration somewhat different. The cohesion between the mineral fragments and the medium used is less with air than with water. This permits a more rapid settling of the fine particles, but in dry concentration it is observed that small particles frequently adhere to larger ones, probably through some electric influence. Particles of great difference in specific gravity differ in speed less in air than in water, and the effect of the greater density of water can be counterbalanced in using air, by giving it greater velocity, for, in jigging, air permits more pulsations per minute than water.

As there are several distinct types of concentrators using water, so are there several using air. In most of these an air current is used having a velocity greater than the free-settling velocity of the lighter material, consequently most of this is blown out of and away from the machine, leaving behind the gold, the other minerals of high gravity and the coarser particles of minerals of medium gravity.

The most elementary form is the *batea* or wooden pan. In using this the air-blast is supplied by the lungs and the implement is manipulated with rotary and other motions which gather the heavy material toward the centre, while distributing the lighter material toward the margin whence it is blown away. The air-blast is varied in force according to the material to be removed and, toward the last, the residue of valueless material is separated from the gold by clever manipulation and blown out of the *batea*.

Next in order is the common Mexican 'dry washer,' a most efficient machine, said to have been introduced by Hungarians about 1850, and extensively used in northern Mexico. This consists mainly of a tray about 1½ by 3 ft., with muslin bottom and 5 cross-riffles resting, at an inclination of about 15°, on a frame, beneath which is a canvas bellows. The latter forces through the muslin an intermittent blast of air which drives away most of the fine light material. The gravel is fed through a hopper upon the upper end of the tray and is moved slowly down the slope by the jar of the bellows stroke. As the operation proceeds the gold lodges on the riffles, chiefly behind the two uppermost, and the material of lower specific gravity flows on over the riffles and gradually passes out of the machine at the lower end. The slope of the latter is increased, when necessary, by blocking up the rear legs, and an inclination of 25° is frequently used.

A machine of this class is usually operated by two men. The common mode of procedure among Sonora *gambucinos* is for the men to spend the morning in mining. One digs out the gravel, while the other turns the windlass if

a shaft is used, or carries out the gravel with a wheelbarrow if working in an adit. As the pay-dirt is taken out, it is spread in the sun to dry, all boulders and stones of appreciable size being removed. After a nooning, the two treat the dirt in the machine. One turns the wheel operating the bellows, adapting the force of the blast to the material, while the other feeds dirt into the hopper, carefully watching its progress over the riffles. When the latter appears to be as well loaded as may be consistent with safety, the bellows is stopped, the tray is removed, after loosening the wedges which hold it in place, and the concentrate is transferred from the tray to a *batea*, where further concentration and cleaning of the gold is done. This machine is thoroughly efficient in the hands of skilled workmen, who are not difficult to obtain. The loss of gold in the tailing is small. The chief loss is in gold so fine that it is blown away with the quartz dust, but the amount of this is usually not great. When built of substantial size, with a tray about 2 by 4 ft., or 2½ by 5 ft., these machines are quite efficient, and, with local labor, entirely satisfactory for limited operations.

The chief advance in the development of this type of machine is an air-jig, put on the market some eight years ago by Steele, Sutton & Steele, of Dallas, Texas. In this the stationary tray is replaced by a revolving table or belt about 3 ft. wide, with riffles about 8 in. apart and screened with muslin. This is inclined about 30°, the slope being adjustable. The operation of this machine is identical with that of the Mexican 'dry washer,' except that the operation is continuous, and as the fine is driven away by the intermittent bellows blast which passes through the muslin, the riffled belt raises the concentrate to the top of the machine and, passing over, dumps it into a box at the rear. In an extended trial of four of these air-jigs, on placer gravel in Sonora, Mexico, I found them very efficient in recovering the gold. A serious difficulty, however, was a lack of durability and a tendency to get out of adjustment, which made it necessary at frequent intervals to stop work for repairs. If this machine were perfected, as it undoubtedly can be, it would be most valuable.

The Curtis machine, made in Denver, Colorado, uses a continuous blast of air from a fan. As usually constructed, each unit consists of a trough-like box, semicircular in vertical section and covered by a perforated plate, somewhat less than an inch thick. The perforations are semicircular in cross-section, and about an inch in diameter. They are partly closed beneath by wire gauze, which allows the air-blast to pass but retains the concentrate. The boxes, which are usually set in pairs on a frame, have a gentle inclination and receive lateral agitation from a cam. The pay-dirt is fed upon the upper end of the plate and, as it passes down the slope, the fine material is blown away and the concentrate is caught in the holes or recesses which serve as riffles, the tailing escaping at the end. To clean up, the machine is stopped and the plate is rotated on a longitudinal axis, dumping the concentrate into the trough below, from which it is removed. The machine has made good recoveries on some material, but requires closer sizing than one-eighth inch.

Another type is the Shumway concentrator, made in Los Angeles. This consists of a shallow wooden box, covered with thin canvas through which a continuous air-blast is forced by a fan. Over the canvas, wire netting of about half-inch mesh is laid. By means of cams the box, which is slightly inclined, is agitated laterally and the dirt fed upon the canvas, at the top of the incline, passes down the slope, leaving the concentrate in the meshes of the wire, while the tailing falls to the ground. To recover the concentrate, the operation of this machine must be suspended and the table tilted for cleaning up. It has done good

work under favorable conditions, but it also requires finer sizing than one-eighth inch. For a time it was used in the Little Florence mill at Goldfield, Nevada.

The Jardine concentrator, made in San Francisco, is the result of a diligent effort to construct a durable machine which is continuous in operation and does not stop for cleaning up. The air-blast comes from a fan, but is made intermittent by a rotary valve. The shallow box which serves as an air-chamber is interrupted across its length by riffles of parallel metal plates with intervening slits which guide the concentrate down into cylinders in which worm conveyors rotate, conducting the gold and heavier materials to a trough at one side. Between the riffles, the surface of the table is formed of a cotton-cloth screen, through which the air-blast passes. Lateral agitation is provided and, as the dirt passes down the sloping table, the fine light material is blown away. The concentrate caught by the riffles is delivered into the trough at the side, and the tailing passes away at the end of the table. A machine of much efficiency has recently been devised by A. H. Stebbins, of Los Angeles. This, in general form and action, resembles closely a Wilfley table. The surface and the riffles are formed from sheet metal, the latter being about 1 in. apart. Air is introduced beneath the table in a continuous blast from a fan, and reaches the bed of dirt through minute perforations in the metal surface of the table. These perforations, which are as close together as possible, are rectangular and about  $\frac{1}{4}$  in. long and  $\frac{1}{40}$  to  $\frac{1}{64}$  in. wide. The longer axes of these slits stand at about  $45^\circ$  to the direction of the riffles. The form of the slit gives the air-jet an inclination of about  $10^\circ$  above the surface of the table, and the air-sheet formed by these jets flows with the dirt in its descent along the slope. It is stated by the inventor that material as coarse as  $\frac{1}{2}$  in. can be treated on this machine, which apparently is destined to be quite successful.

The total number of machines devised for this work can probably be reckoned by hundreds. Most of them have been short-lived. Those mentioned above are a few of the most promising which have come to my attention. To successfully solve the problems of the dry concentration of placer gravel, the machine employed must meet several conditions, and, on the other hand, certain conditions are necessary in the material to permit any machine to work successfully. The concentrator must be capable of working effectively on material of all sizes up to  $\frac{1}{8}$  in. This mesh has been determined for many localities in Sonora, as one which will allow most of the coarse gold to pass through with the fine. Should there be much coarse gold present in the gravel, the screen must be made proportionately coarser, and the concentrator must work on coarser material. Primarily the pay-dirt treated must be dry. Average uncemented placer gravel as it occurs, even in the dry climate of Sonora, is usually too moist, when mined, for immediate treatment. The *gambucinos*, working on a small scale, dry their dirt by spreading it in the sun. To do this on a large scale would invite theft. In many cases it is necessary to provide mechanical drying, but this involves no serious difficulty in labor or expense. Cemented gravel usually carries less water than that which is uncemented, but it requires crushing and screening to bring it into the required condition for treatment. The heat generated in the pul-

verizer serves to remove the small amount of moisture present.

The gold in the cemented placer gravels does not occur within the pebbles, boulders, and rock fragments, but on their surfaces, being practically all included in the calcareous cement which unites them. The first step in treatment must, therefore, be the separation of the barren rock fragments from the gold-bearing cement and the pulverizing of the latter. This is done with great efficiency by the Quenner pulverizer, which consists of a revolving

DRY CONCENTRATION PLANT, BOLUDO.

DRY CONCENTRATION PLANT NEAR LLANO, SONORA.

trommel or barrel of steel staves with a shaft rotating independently within and carrying chain hammers. These hammers effectively break up the calcareous cement and leave the cobble-stones and pebbles with nearly clean surfaces, to be ejected at one end of the barrel, while the pulverized cement escapes through the quarter-inch spaces between the staves. Thus in many localities the material subjected to dry concentration for the recovery of the gold is only about one-half of the total mined. Credit for the invention of this machine is claimed by Joseph Lusignan, a French Canadian living in Nogales, Arizona, and a man of much mechanical ingenuity and skill, but Mitts Quenner, a Sonora miner, exploited the machine commercially and profited by his business shrewdness.

Concentration with air introduces a detail which does

not have to be considered in using water, as a cloud of fine dust rises from the dry concentrator, which is very irritating to the eyes and lungs. The best way to dispose of this is to cover the table with a hood, which catches the dust and delivers it to an exhaust fan. As most of the fine dust is blown out of the dirt near the upper end of the table, it is unnecessary for the hood to cover the whole of the latter. Sufficient of the lower end may be left uncovered to give a view of the action of the machine.

During the past four years I have attentively studied various methods of dry concentration in work carried on under my own supervision and in operations conducted by others, and my observations convince me of the commercial practicability of this treatment. Thus far, the Mexican 'dry washer' is the only machine which has been successfully used in treating dry placer gravel on a commercial scale in Sonora. Several other machines of small capacity have been used in individual enterprises with some success, but up to the present time no one has made a continuous demonstration in practical operation of any of the newer types of dry concentrator, yet undoubtedly some one of them will soon be perfected and will prove efficient. A machine made by J. M. Wishart, of Pasadena, is being used on the border of the Mojave desert near Victorville, but I have not yet seen it. It is not probable that, in concentration, air will compete with water where the latter may be freely obtained, but dry concentration is necessary for the recovery of millions of dollars in gold lying in the Tertiary and Quaternary gravels of the arid areas of Sonora, Arizona, New Mexico, California, and Nevada. At but few points do these placer deposits occur in sufficient extent to justify the expense of erecting plants for pumping water long distances, but, in a hundred or more of them, there is sufficient gold to justify an expenditure of from \$5000 to \$15,000 for equipment. Most of these, with careful management, will give ample return, while a few will yield substantial fortunes.

## Short-Circuiting in Anode Tanks

By A. R. LEDOUX

Some years ago the head of one of the most important electrolytic refineries in the United States was puzzled to discover the cause of certain short-circuits. He noticed that an accretion started at the anode and grew always from one side of the anode toward the cathode until it had completed a short-circuit. The works ran north and south, and this short-circuiting was always from the west toward the east. The manager came very near making a statement before a scientific society that the revolution of the earth must have something to do with this short-circuiting, as it always was in the direction from the west toward the east; but one day he broke off one of these fingers which ran across, and found, at the point where it began, a little splinter of wood. He broke off others and found the same thing; and, to make a long story short, the reason was just this: The anodes, which were heavy, were brought into the factory, unloaded from a car and dumped by the men on a block of wood alongside of the tank. They did it always the same way; the corner of the anode always struck the wood at a certain inclination, and little splinters of the wood were broken off and adhered to the bottom of the anode. When the anode was put into the tank (always in the one way), that splinter served as a starting point for a short-circuit, and that was the simple solution of something that had been bothering them for more than a year. When they substituted a rubber mat for a wooden block, the trouble ceased.—*Bulletin of the A. I. M. E.*

COPPER ORE and pyrite valued at \$2,010,000 was produced in Norway in 1911. Nearly all of this was exported and the chief value was in pyrite, the copper being valued at \$470,000. Some 4000 people are engaged in mining this ore.

## The Cuyuna Iron Range

By KIRBY THOMAS

More than 2000 drill-holes have been sunk in the Cuyuna iron district of Minnesota in the past five years to find and explore the bodies of iron ore which were hypothetically located by Cuyler Adams from assumptions based on certain disturbances of the magnetic needle in the region. The whole area is covered with a glacial mantle from 50 to 100 ft. thick, and there are no rock outcrops to give any indication of the formation of ore within many miles of the orebodies now being disclosed. It is true that about 1890, R. D. Irving suggested that the iron-bearing formation should be found in the approximate region of the Cuyuna district, basing his suggestion on the obvious relation between the Keewenaw eruptive beds forming the vast Lake Superior synclinal trough and the older and underlying sedimentary beds in which several of the Lake Superior iron formations occurred, and later C. R. Van Hise and C. K. Leith, of the U. S. Geological Survey, more definitely accepted the hypothesis and mapped a projection of the iron-bearing formation approximately in the line of the later discovered Cuyuna deposits. It now develops that these hypotheses were only correct as applied generally, for the Cuyuna deposits seem to be rather related to the Crystal Falls, Michigan, area geologically, than direct extension of the Mesabi formation or correlating with the Penokee-Gogebic formation, a matter of academic interest. The purpose here is to present the method and results of the exploration after once the orebody was found and the factors in the interpretation of the large amount of data made available from drilling and lesser amount from the underground work.

The first drill-holes were sunk on the lines of maximum magnetic attraction, which had been platted with fair exactness. The results were disappointing, for the cores showed only lean schist with magnetite. With a knowledge of the general geology of the Lake Superior deposits, this information was significant, if not definite. Other drill-holes were sunk to the south at right angles to the line of the maximum attraction, and ore was found. This ore was hematite, and hence did not itself affect the magnetic needle, but the facts from these first drill-holes furnished the key to a new and important iron district, and added many millions of tons to the discovered ore reserves of the Lake Superior region. Further drilling disclosed that the ore was not in flat blanket-like bodies as on the Mesabi, but was in beds dipping from 60 to 70° to the southeast with the general rock formations of the area, and, in fact, forming part of the rock formations structurally. It was then further determined that the ore in depth changed to iron carbonate, mostly, representing the unaltered iron formation member of the geologic series, and that the orebodies were not continuous along the strike, but were lenses or interrupted parts of the beds coming to the erosion surface. Other approximately parallel lenses or beds were disclosed by more drilling on both sides of the magnetic schist member. Evidences of a pitch or hade of the orebodies was also present, indicating a complex folding to form the trough and saddle-shaped orebodies characteristic of the synclinal and synclinal ore structures. Another range, so called, to the north was later found by drilling on the magnetic indications, and this was found to include several parallel beds. The whole disclosure so far indicates a broad system of folding of iron formation and the genesis of iron orebodies from the iron-bearing members at physically favorable places. It was also determined that eruptive dikes and bosses intercepted the sedimentary iron formations in places, and it was anticipated that these eruptive formations would have a bearing on the orebodies. All this was worked out before any shaft was sunk to give visible confirmation of the theories based on the drill data.

Most of the drill-holes were sunk vertically, but later, when it was determined that the orebodies had a regular

pitch to the southeast, angle holes to cut the beds at right angles were driven, with the result of checking the data from the vertical holes and giving a basis for the calculation of tonnage and definition of the limits of the orebodies.

Now half a dozen shafts have been sunk to the ore, and the district is a reality, but its discovery was due to a mere theory and its first proof wisely placed drill-holes. The work of exploration was in the hands of men familiar with the general iron formation of the region and with drilling, and competent geologic talent was always at hand to guide and to interpret the facts. The district has been proved for more than 35 miles along the formation, and an iron district potentially as important as any one of the others in the Lake Superior region has been found.

## Alumina as a Drying Agent

By F. M. G. JOHNSON

In the course of an investigation on phosphonium compounds a drying agent was necessary which would successfully dry both  $\text{PH}_3$  and  $\text{HI}$  or  $\text{HBr}$ , since  $\text{P}_2\text{O}_5$  proved useless for this purpose. Satisfactory results were obtained by employing  $\text{Al}_2\text{O}_3$  prepared by igniting the hydroxide at a low temperature. A test of the efficiency of this substance to take up moisture was made by passing air saturated with water vapor at room temperature, about  $18^\circ$ , through a tube containing about 7 gm. of the oxide, and then through a second tube filled with  $\text{P}_2\text{O}_5$ . The air was led through at the rate of about 2 or 3 bubbles per second. Both tubes were weighed from time to time. The somewhat remarkable result obtained was that the  $\text{P}_2\text{O}_5$  tube showed no perceptible gain until the  $\text{Al}_2\text{O}_3$  had increased about 18% in weight, corresponding to the formation of the hydrate  $\text{Al}_2\text{O}_3 \cdot \text{H}_2\text{O}$ . The reaction is generally represented by the equation

The formation of the hydrate is accompanied by evolution of heat, hence increased temperature causes its dissociation into  $\text{Al}_2\text{O}_3$  and  $\text{H}_2\text{O}$ . It is thus seen that 1 gm. of  $\text{Al}_2\text{O}_3$  can practically completely absorb all moisture from approximately 10 litres of air saturated with water vapor at  $18^\circ$ . G. P. Baxter and R. D. Warren investigated the drying properties of  $\text{CaBr}_2$ ,  $\text{ZnBr}_2$ , and  $\text{ZnCl}_2$ , and their results show that compared with  $\text{Al}_2\text{O}_3$  these substances are much inferior as desiccating agents.  $\text{Al}_2\text{O}_3$  is also more effective than  $\text{H}_2\text{SO}_4$ . A tube filled with  $\text{Al}_2\text{O}_3$  can be used for an indefinite period, if from time to time it is heated with a smoky flame while air, previously led through  $\text{H}_2\text{SO}_4$ , is passed through it. To replace the usual  $\text{P}_2\text{O}_5$  tube used in connection with mercury pumps it appears particularly suitable, since the tube used need never be renewed. A small tube of  $\text{P}_2\text{O}_5$  following the  $\text{Al}_2\text{O}_3$  would serve to indicate when the  $\text{Al}_2\text{O}_3$  needed reheating. Its uses in many investigations are obvious.—*Journal Amer. Chem. Society.*

PRODUCTION of manganese ores in 1911, according to E. F. Burchard, of the U. S. Geological Survey, was 2457 long tons, valued at \$24,586, a slight increase over the figures for 1910. The ore was mined in California and Virginia. The importation of manganese ores continues to greatly exceed the domestic production, and will probably continue to do so as long as the principal sources of foreign supply are abundant and cheaply worked, and ocean freights are low. In 1911 the imports were 176,852 long tons, valued at \$1,186,791, a decrease of 65,496 tons as compared with the importations for 1910. This decrease in the demand for manganese is attributed to the depression in the iron and steel industry.

TIN production of Bolivia in 1911 amounted to 24,000 tons, as compared with 22,855 tons in 1910 and 21,340 tons in 1909.

COAL deposits have been discovered in Neuquen territory, Argentina, by a Government expedition.

## The Coal Supply of Manchuria

By EDWARD DI VILLA

The only coal mines of importance at present worked in Manchuria are the Fushun mines. These mines rank among the largest in China, with an average output of about 4000 tons per day. From October 1908 to August 1911 the exports from this mine amounted to 349,577 tons, of which Japan received 17,844 tons, Korea 101,276, China 210,332, Europe 4251, the South Seas 15,811, and America 3 tons. The coal seam is 130 ft. thick. The mine is situated close to Mukden, and a glance at the map of Manchuria will show that this mine can command the market of practically the whole of South Manchuria. The output of the mine is to be raised to 2,000,000 tons per year. The area of Manchuria is 400,000 square miles, and the population is about 13 millions, of which 6 millions are under Japanese influence.

Manchuria may be roughly divided at present into three

COALFIELDS OF MANCHURIA.

parts. The northwest is under Russian influence, and wood is the principal fuel used, even on the Chinese Eastern railway. The southern terminus of the Russian railway is at Kuanchengtze. From Kuanchengtze south 436 miles to Dairen the railroad is operated by the Japanese, and coal from the Fushun mines is used. The eastern part is still somewhat Chinese. The natives chiefly burn dry corn stalks and other refuse vegetation. A line is now in course of construction from Changchun to Kirin. This is a joint Chinese and Japanese undertaking, and coal is the fuel used. Unfortunately for the Chinese, the only place from which they can purchase their coal is from the Fushun mines, which are entirely Japanese. In case of any trouble between the Chinese and Japanese, the coal supply of the railway would naturally be stopped. In order to remedy this sad lack of foresight on the part of the Chinese Government at Peking, I spent three months in Manchuria examining the geological conditions in the vicinity of the new railway line. The length of the line is 84 miles, the ground is undulating, with a small range of hills to be crossed about half way. Five suitable places were discovered where coal-mining might at present be profitably started.

Among these, the most advantageously situated is one in a district called Huo-shih-shan, about 30 miles east of Changchun and one mile from the line of the Kirin-

Changehun railway. The land surface between the mine site and the railway line is nearly level, and is such that a branch line two miles long could be constructed with maximum gradients of 1%. The gradients on the K. C. R. are 1%. Some seams of coal outcrop in a small range of hills having a due east and west trend. The natives have worked the coal to a small extent, confining their operations to the surface. The hand specimens obtained are 'semi-anthracitic, tending toward bituminous varieties, contain some occluded gases, and are inclined to be shattered.

The first seam of coal is overlain by a coarse-grained grit. This grit is very interesting, as it is similar to the grits overlying the Carboniferous formations of the northern coalfields of England. Another grit, similar to the above, is finer grained. The upper grit is composed of practically pure quartz, with a few glistening scales of muscovite mica, and in a matrix of kaolin, the quantity of kaolin exceeding that of the quartz. The lower grit has a larger percentage of kaolin, about 65 to 70. The quartz is angular and sharp, and viewed under the microscope is full of fluid cavities. In the upper grit, needles of tourmaline are of frequent occurrence. This grit is probably a decomposition product of granite. The quartz crystals show no sign of abrasion. The sizes of the crystals vary from 1/15 inch in the upper grits to 1/125 inch in the lower grits. These grits are not very hard, and in places they contain some very thin seams of coal of light grayish color. The thickness of the upper grit is 30 to 40 ft.; under this occurs a seam of coal 5 ft. in thickness. Next follows the finer grit, which has very fine clay partings and is 2 ft. thick; then comes a seam of coal 7 ft. thick. I have no doubt that there is more coal underneath, as there is no marked change in the character of the rock underlying the last seam of coal mentioned.

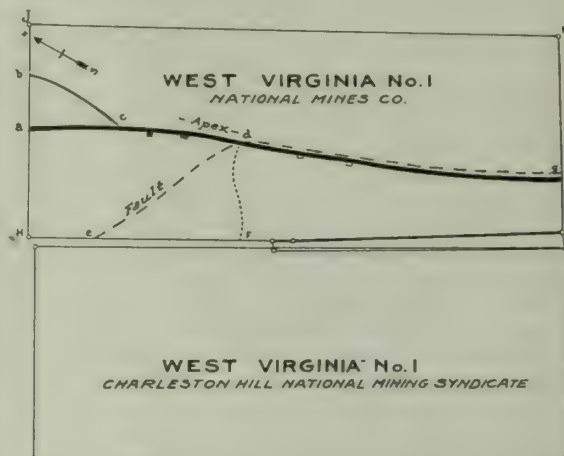

I was able to trace the seams of coal for several miles, but did not manage to collect any fossils, as these do not interest the natives. I promised to reward them for any fossils they would bring me. The district around is very poor and land very cheap. Labor would cost about ₧0.50 per day average. Water is not abundant in the district; there are, however, two small creeks nearby. In the villages wells nearby the depth to water is 30 to 40 ft. Timber is abundant. There would be an excellent market for coal in the neighborhood for the railway and up to Harbin. The selling price in Kirin and Changehun would be about \$5 small coin (say \$2) per ton of 2240 lb. I was unable to remain in this district as long as I should have liked, as I had to return to Tientsin on the outbreak of the revolution in November 1911. Under proper management these mines could be profitably worked, and with no small advantages to the railway.

## Electric Pig Iron Production at Trollhattan

The electric furnace for the production of pig iron, at Trollhattan in Sweden, has been in operation for eighteen months, and the results of operations during a 215-day continuous run have recently been made public by J. A. Leffler and E. Nystrom. The iron ore used averaged 61% Fe for the run and was fed to the furnace at the rate of 24.5 tons per day, together with 6 tons of charcoal (containing 73% carbon) and 1.8 tons of unburned limestone (54.3% CaO). The daily production of pig iron was 15 tons, the power consumption per ton of pig iron being 1482 kw., and the electrode consumption 12 lb. per ton of pig. The average composition of the pig iron for the period was: C, 3.046%; Si, 0.725; Mn, 0.477; S, 0.0126; P, 0.02%. The e.m.f. on the furnace was 73.6 volts, and the current 11,423 amperes. The output of iron per kilowatt-year was 3.94 tons. The gases are drawn off at the top of the furnace and forced in again at the tuyere level, thus carrying the heat up the shaft to effect reduction; one-third of the heat generated is thus transferred. Many problems of operation still remain to be solved.

## Litigation at National

We present below a sketch of the ground at National, Nevada, now in dispute between the National Mines Co. and the Charleston Hill National Mining Syndicate. The first named company is the owner of the West Virginia No. 1 claim, from which extremely rich ore has been mined in the past two years. The company claims the apex of a vein bifurcated at the north, as shown, but continuing to the end of the claim as indicated. On the other hand, the Charleston Hill Syndicate claims a fault line as indicated from *e* to *g*, and that the apex is from *a* to *d* on the surface and from *d* to *f* underneath the fault plane. According to this contention, the southern two-thirds of the 'apex' of the vein is really the apex of a fault later in time than the fissure in which the National vein is found. It is also

claimed that the fault cuts and dislocates the National vein. The two fissures are extensively developed by underground workings, and the fact that the drifts run without break from the recognized National vein into and along the fault claimed, is admitted. It is also true that the valuable ore has been found in the workings north from the intersection of the vein and the fault. It was at first maintained by the experts for the National company that there was no fault, but in later testimony doubt was thrown on this and emphasis placed upon the period of mineralization, which was held to be contemporaneous in the 'vein' and the 'fault,' making the whole one continuous vein. The case is still in process of trial. The experts for the National Mines Co. include Messrs. H. V. Winchell, A. N. Winchell, H. L. Hollis, W. H. Wiley, and others, while for the Charleston Hill Syndicate the principal experts are Messrs. Albert Burch and A. C. Lawson.

MASSIVE, finely granular rhodonite occurs at many localities in California, and some of them have yielded gem and ornamental material. The different deposits yield a similar product, the chief difference being in richness of color. Black manganese oxides are associated with much of the rhodonite, filling seams and cracks, and make pretty contrasts with the pink. Probably the best gem material so far found has come from the Wheeler prospect, about nine miles north of Happy Camp, in Siskiyou county, but good material has been found near Taylorsville, in Plumas county, and other localities. These rhodonite deposits are associated with sedimentary rocks and occur along belts of manganese-stained slates and quartzites.

FURNACES at the plant of the Han-Yeh-Ping Iron & Coal Co. at Hankow, China, are now in operation again and it is expected that full operations will be resumed this month.

NITRATE exports from Chile for the past four months of 1912 paid taxes amounting to \$9,830,130, as compared with \$8,471,650 in 1910.

## Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

### Smelting and Refining Zinc-Box Precipitate

The Editor:

Sir—In your issue of March 2, M. W. von Bernewitz has an interesting article on the treatment of matte and sulphur refining, but I am by no means convinced that the method of smelting the matte with cyanide and borax is the most convenient or best. Lately I have not had any matte to handle, having come to the same conclusion as Mr. von Bernewitz, that it is a nuisance and that its formation is best avoided, but, some time since, I did a good deal of sulphur refining, of which the following are typical examples: Crude bullion from cyanide clean-up, weight 171.7 oz. Assay value: gold, 518.5, equivalent to 89.03 oz.; silver, 264.2, equivalent to 45.37 oz.; base, 217.2, equivalent to 37.30 oz. This bullion was now melted, keeping the heat as low as possible, in a 30 'salamander' crucible, and 15% of its weight of sulphur added, stirring with a salamander rod. The large crucible was used to give plenty of surface and to avoid loss through spitting. The use of a small clay crucible inverted over the sulphur, described by Mr. von Bernewitz had been previously tried and abandoned, as it was thought the action was too violent and that some gold was lost by spitting.

The resulting bullion weighed 92 oz., assaying: gold, 813.9, equivalent to 74.878 oz.; silver, 139, equivalent to 12.788 oz.; base, 47, equivalent to 4.324 oz. The resulting matte, weighing 93.8 oz., was smelted in a hot fire with iron, no other addition being made except a little borax. The resulting bullion weighed 49.4 oz., assaying: gold, 301.4, equivalent to 14.8 oz.; silver, 548.2, equivalent to 26.9 oz.; base, 150.3, equivalent to 7.7 oz. The resulting matte weighed 51.8 oz., assaying: gold, 16.45, equivalent to 0.52 dwt.; silver, 10%, equivalent to 5.18 oz.; copper, 35%, equivalent to 18.13 oz. The matte was not treated further, but shipped to the smelter with the slag. It will be seen that the bullion assays do not agree exactly, owing to the difficulty of getting a fair average sample of the low-grade bullion by boring; it should have been sampled by dip samples.

The net result of the sulphur refining was to reduce the base metal from 37.3 to 12 oz. and to lock up 5½ oz. silver and ½ dwt. gold in the matte. The following is a summary of this and of two other lots of bullion treated in a similar manner:

	Bullion, oz.	Au, %	Ag, %	Base, %	Au, %	Ag, %	Base, %	S added, oz.	
Crude bullion .....	171.50	51.85	26.42	21.72	89.03	45.37	37.30	24	15
After first S treatment.....	92.00	81.39	13.90	4.70	74.87	12.78	4.35	..	..
Bullion from matte.....	49.40	30.14	54.82	15.03	14.80	26.90	7.70	..	..
Residual matte contains.....	....	0.05	10.00	Cu 35.00	0.026	5.18	Cu 18.13	..	..
Crude bullion .....	238.00	46.13	35.32	18.34	109.90	84.50	43.60	24	10
After first S treatment.....	183.75	59.89	31.82	8.28	110.04	58.47	15.24	24	13
After second S treatment....	150.75	70.49	25.68	3.82	106.26	38.73	5.76	7	5

Bullion from matte.....	27.25	17.96	72.08	9.95	4.89	19.64	2.71	..	..
Residual matte contains.....	....	0.05	12.18	....	0.021	5.28	....	..	..

This shows that the 'iron' method of treating matte is effective in recovering gold, but the resulting bullion is too base, requiring further refining, and a notable quantity of silver is locked up in the matte. It seems to be more effective than the cyanide method and is certainly easier,

no pulverizing of the matte being required, and cheaper, no cyanide and but a very little borax being needed.

Not being satisfied with the sulphur treatment, I thought that if the precipitate were slightly roasted before acid treatment, in order to oxidize and render more soluble the base metals, a residue would be left containing little base metal, and smelting charge would be reduced. This was found to be the case, with the additional advantage that there was no foaming, as no hydrogen was evolved, less acid was required, as part of the zinc was volatilized, and any white precipitate was decomposed by the roast and rendered more soluble. On the other hand, there was the possibility of loss of precious metals in roasting. I was skeptical as to there being any serious losses, but to determine the matter to my own satisfaction, I made the following experiments. A difficulty in carrying out work of this class arises from sampling, it being almost impossible to get accurate samples of such rich stuff; however, all reasonable precautions were taken and six determinations were made to reduce the chance of error as far as possible.

After roasting or treating with acid, the samples of precipitate were fluxed as follows: precipitate, 100 parts; litharge, 50 parts; borax, 50 parts; soda, 25 parts. The slag was then cleaned by smelting with more litharge and iron, and the lead bullion cupelled, and assayed. The precipitate experimented on was from the treatment of an old slime dump and was essentially low grade.

#### EXPERIMENTS ON SHORT ZINC

		Au, gm.	Ag, gm.
1a	500 gm. ppt. after roasting yielded.....	11.84	10.51
1b	" " " acid treatment.....	12.14	11.06
2a	" " " roasting .....	7.77	7.26
2b	" " " acid treatment.....	9.69	8.22
3a	" " " roasting .....	6.92	5.95
3b	" " " acid treatment.....	8.43	7.02

Average loss by roasting: gold, 12.3%; silver, 9.9%.

The apparently smaller loss of silver was probably due to some being dissolved by the sulphuric acid.

#### EXPERIMENTS ON FINE PRECIPITATE

		Au, gm.	Ag, gm.
4a	500 gm. after roasting yielded.....	15.10	13.02
4b	" " " acid treatment.....	13.97	14.59
5a	" " " roasting .....	10.84	10.52
5b	" " " acid treatment.....	11.08	10.53
6a	1000 gm. " roasting .....	40.02	37.94
6b	" " " treatment with lead acetate to replace zinc and smelted without either acid treatment or roasting .....	43.14	42.50

Average loss of gold by roasting, 3.3%; silver, 8.8%.

Here the loss of gold by roasting is much reduced, but

the silver loss is relatively higher, probably owing to No. 6b not being acid treated. In the six parcels treated, five gave higher results without roasting, and in the case of the sixth (No. 4a) the combined weight of gold and silver was higher in the non-roasted portion, and it is

possible that an error occurred in assaying the bullion, parting may have been imperfect. Roasting was effected in an iron pan over a fire; possibly with a more perfect roasting arrangement the losses would be materially reduced.

It seems probable that nearly all the advantages of roasting before acid treatment could be obtained by subjecting the damp precipitate to treatment in a chamber with warm air saturated with moisture and a little acid vapor (acetic acid would probably be suitable), somewhat on the lines of the old Dutch process of white lead manufacture. All the metallic zinc and copper would be readily oxidized and rendered soluble in dilute sulphuric acid, but it is doubtful whether the expense of this preliminary treatment would in many cases be justified.

The dried precipitate, after acid treatment, is in a finely divided state, and is specially suitable for smelting with an oxidizing flux. My present practice is to smelt with  $MnO_2$ , borax, sand, and fluorspar, obtaining a bullion that averages about 3% base metal. The silver is to a considerable extent carried into the slag, but that is locally no disadvantage, as the mint allows only 1s. 9d. per ounce for fine silver, while the combined bank and mint charges are 1s. 2d. per ounce, and as the slag has in any case to be shipped to the smelter, it is more profitable that it should have a high silver content.  $MnO_2$  acts more energetically than nitre, and does not boil up so much, nor does it seem so corrosive on crucibles. Bessemerizing by air was first tried and patented by Manton, of Menzies, but the corrosion both of the air-pipes and of the crucibles was excessive, and until Rose published his classic paper on this method, no really conclusive work had been done to prove that there was no appreciable loss of precious metals.

H. R. EDMANDS.

Menzies, Western Australia, May 10.

### Mine-Owners' Liability for Accidents

The Editor:

Sir—Among managers of plants there seems to be a widespread impression that if the mine manager adopts the compensation system he does not relieve himself from the possibility of a damage suit undertaken by the workman through a contingency lawyer. It may be well to point out the facts in regard to this, as there seems to be a good deal of misunderstanding about it.

The concluding paragraph of section 3 of the Roseberry law reads in part as follows: "And where such conditions of compensation exist for any personal injury or death, the right to the recovery of such compensation pursuant to the provisions of this act, and acts amendatory thereof, shall be the exclusive remedy against the employer for such injury or death, except that when the injury was caused by the personal gross negligence or wilful personal misconduct of the employer, or by reason of his violation of any statute designed for the protection of employees from bodily injury, the employee may, at his option, either claim compensation under this act, or maintain an action for damages therefor." Through the pernicious activity of insurance solicitors the most that can be made of the phrases "personal gross negligence" and "wilful personal misconduct" has been made of them to frighten employers from accepting the compensation provisions of the Roseberry act, lest by doing so they undertake to carry their own insurance under the protection of the limited liability which those provisions afford.

Nearly all laws relating to this subject, in nearly all countries, retain these exceptions for the punishment of that relatively small number of employers who do take less care of their men than they do of their mules, and who need the restraining influence of a possible mulct in exemplary damages in retribution of their culpable disregard for the welfare of their men. The compensation laws of Great Britain, and of all of its colonies, preserve this right to the injured person as an inalienable right of Englishmen to have a personal wrong done them redressed through the courts, that reparation may be made

them to the full measure of all that they have suffered. Our compensation law has been derived, in the main, from the British laws on the same subject.

On the continent of Europe, and in Germany especially, it is a prerequisite to such a suit for damages outside of the law of compensation that the guilty employer be first convicted of criminal conduct toward his employees, after which the injured employee may sue for damages in addition to his compensation. But this is all of more academic than practical value. Not many employers are guilty of personal gross negligence or wilful personal misconduct toward their employees. Even in Great Britain, where the right of an injured employee to avail himself, after the accident, of any remedy he chooses, exists without limitation, out of 282,000 injuries compensated during 1910, only 217 injured persons elected to sue outside of compensation.

In view of the exaggeration and general misconception of the value of these clauses in the statute, I (and I think that my associates on the Industrial Accident Board agree with me) am of the opinion that these provisions should be so far modified as to permit the Industrial Accident Board, in those cases where injuries have been inflicted through the gross personal negligence and wilful personal misconduct of the employer himself and none other, to double the compensation benefits or increase them in reparation for the injury inflicted to not exceeding double such benefits, coupled with a provision which will prohibit insuring against that species of liability. For the punishment should be visited upon the employer, and him only. He should not be permitted to distribute any loss occasioned through his own culpable misconduct either to his industry, through insurance, or to the consuming public through an increase of price. The penalty should be upon him, and sufficiently deterrent in its character to make the unhumane employer humane per force in default of innate decency and sympathy for his kind in his own makeup.

So far I have heard of no instance under the law of personal gross negligence or wilful personal misconduct upon the part of any employer in the treatment of his men, although among those outside of the law, many instances have come to my knowledge where there was gross personal negligence and wilful personal misconduct toward those who were hurt, after they were hurt if not before, and I am fearful that no ease will develop under the law which will permit a judicial construction of what those terms mean. They have been useful mainly to frighten employers into taking liability insurance who would otherwise have accepted compensation and carried their own insurance, and I do not expect them to have any other effect whatsoever. I hope that the next Legislature will so far modify these provisions as to make them less of a bogie.

A. J. PILLSBURY.

San Francisco, June 21.

EMERALD is ranked among the few really precious stones and by some people is considered the most valuable. It has been prized from early times because of its beauty and rarity. The number of localities where good gems have been found is few, and some of those once known have been forgotten. Emeralds found with the mummies of Egypt probably came from the mountains along the west coast of the Red Sea in Upper Egypt, where ancient workings were discovered during the nineteenth century. Mines in the Salzburg Alps are said to have been worked intermittently for emeralds since the time of the Romans to the present. The world's principal supply of emeralds has come from South America. They were first brought to Europe from Peru by the Spaniards in the sixteenth century. None are now found in that country, and it is thought that the Peruvians obtained them from Colombia. Later two of these were lost, and for many years the only mines worked were those near Muzo. Recently the lost mines of Somondoco were found on the east side of the Andes mountains at an elevation of about 9000 ft. above sea-level.

## Special Correspondence

### KALGOORLIE, WESTERN AUSTRALIA

HORSE-SHOE ORE.—ASSOCIATED NORTHERN LEASING.

Among important developments, the Horse-Shoe has now 30 ft. of \$6 ore on the No. 4 lode at 2650-ft. depth. The Associated Northern is now entirely in the hands of tributaries, it paying the company better to collect royalties than to bother with small ore-shoots. The mill is working on custom ore and should be able to keep busy for a number of years. The fall in price of Ivanhoe shares was disturbing, but the bottom levels unquestionably appear doubtful. At the Chaffers-Main Reef an interesting bit of work is under way in the reclaiming of gold from the dump at the roasting plant. It will be remembered that some years since an unsuccessful attempt was made to treat this material by agitation and filter-pressing, the main reason for the failure being the absence of the expected gold. The present plan of operation is to break the lumpy material in a disintegrator, mix it with water, and pump it to a floor which has been laid with tarred canvas to prevent leakage into the ground. The clear water is drawn off at one corner, cyanide added, and the gold precipitated with zinc as usual. Evidently the soluble gold will be thus recovered cheaply, but how much is present is a question.

### LONDON

DECLINE OF SMELTING INDUSTRY OF ENGLAND.—SECOND SIGHT AT THE ST. IVES CONSOLIDATED.

A few months ago I recorded that one of the ten smelting plants in Cornwall had been closed, namely, that belonging to the Bolitho family at Chyandour, Penzance. An even more important event is the suspension of the Pembrey copper works at Burry Port, South Wales, owned by Elliotts Metal Co. It is not the want of enterprise, business and scientific ability, or capital that causes the smelting industry to leave Great Britain. The Pembrey works belonged to Birmingham people, chiefly the Elkingtons and Chamberlains, and the equipment was kept up-to-date, but the difficulty of buying copper, lead, and silver ore, matte, and bullion has gradually increased. The smelting and refining industries have gone to the mines, and the British user of metals can no longer be his own producer. The Pembrey works are to be sold at auction next month, and it is probable that they will pass to other industries than smelting and refining. Probably the few remaining copper and lead custom smelters in South Wales will follow suit when current contracts expire. As regards the zinc furnaces, there is still a good deal of activity, but expansion is unlikely owing to labor troubles.

A month ago I sent some details of the want of real progress by the St. Agnes Consolidated, one of the Schiff-Dietzsch group of companies operating in Cornwall. This week a bombastic circular has been issued relating to the happenings at the St. Ives Consolidated, another of the group. I cannot do better than quote the words of the circular. It relates to a report made by Charles M. Rolker, a mining engineer well known in America as the consulting engineer of the Natomas Consolidated, and in Russia as consulting engineer to the Lena Goldfields. The secretary says: "I am directed by my Board to inform you that they have received a satisfactory report from Charles M. Rolker, embodying his recommendations and views on the future probabilities of the company's mines, based on the exhaustive examination made by him during January and February of this year. In his report Mr. Rolker states that the object of the St. Ives Consolidated Mines, Ltd., to reopen these mines and, after freeing them from water, bring them to a producing stage as far as tin ore is concerned, and to search for pitchblende ores in the Trenwith mine, seems a justifiable and legitimate undertaking. He further expresses the opinion that when the Consols mine is unwatered and virgin ground entered, ore averaging 40 lb. black tin per ton

may be expected within ore-shoot limits, and that 30,000 tons of ore of this grade sent to the mill with a 20s. cost per ton of ore gives £18,994 profit per year."

I would draw attention to the extraordinary opinion in the above paragraph, to the effect that an unexplored block of ground will provide ore averaging 40 lb. of black tin per ton. Some years ago it was said by a popular paper in England that John Hays Hammond was such a clever engineer that he could appraise the value of a mine without seeing it, but are we to believe that Mr. Rolker, who is such a precise man, really expressed the opinion that virgin ground in a waterlogged mine would yield 40 lb. ore, and in sufficient quantity to warrant calculations involving a production at the rate of 30,000 tons per year? Apparently the days of Albert Grant, Whitaker Wright, and Horatio Bottomley are not over for good and all.

### RHODESIA

GOLD OUTPUT.—GLOOMY OUTLOOK FOR LABOR SUPPLY.—FAILURE OF THE BUCK'S REEF.

Th gold output of Southern Rhodesia for the month of April has been declared at 52,587 oz., of a value of £221,476, as compared with 51,072 oz., worth £215,102, in the preceding month. Other minerals produced during April were: Silver 14,181 oz., coal 13,156 tons, lead 51 tons, and chrome-iron ore 6188 tons. But little increase is to be observed in the gold production, and no really material expansion

A RHODESIAN PROSPECT.

sion of output can be expected until the Shamva at Abercorn, the Cam & Motor on the Eiffel Flats, the Golden Kopfe, the Eileen Allannah, the Falcon, and the Antelope enter the productive lists. These concerns have been developing for a long while and have developed large tonnages of ore. Their advent as producers will have a marked effect on the gold output of the country. Each of these mines should be producing toward the end of next year. The larger mines of the country which are operating stamp-batteries go on in a humdrum sort of way. The smaller properties, operated by tributors and small syndicates, are the flotsam and jetsam of the industry and while in one month increased return may be recorded from these sources the succeeding declaration, on the other hand, show a substantial decline.

Much, of course depends on the labor position. So far as can be judged, the new Rhodesian Native Labor Bureau has not up to the present improved it at all. A serious feature is the opposition to the recruiting efforts of the Bureau in Northern Rhodesia by the farming community to the north of the Zambesi. In northwestern Rhodesia agriculture is making slow but steady progress and it is alleged by the farmers that the supply of native labor is not sufficient for their purposes. One or two meetings have been held and vigorous protests have been lodged against the operations of the Rhodesian Native Labor Bureau in the northern agricultural districts. The path of the Bureau is certainly not strewn with roses. The Imperial Government has vir-

tually closed the door to recruiting in Nyassaland. In Portuguese East Africa the Bureau has to compete with the wealthier organizations of the Witwatersrand. The Transvaal and other states of the Union are closed to Rhodesian recruiters, but little labor is forthcoming in Southern Rhodesia itself, and now the northern territories are agitating for the expulsion of the R. N. L. B. Unless more local and Portuguese African labor is obtained it is difficult to see where the natives necessary to operate the large plants starting up shortly will be found.

The profitable ore reserves of the Buck's Reef Gold Mines have dwindled to 3650 tons, or only five months' supply at the present much-reduced rate of crushing. Recent development has been distinctly disappointing and it must be admitted that this property, of which such great things were expected a year or two ago, is a failure. It is in many ways regrettable that it was ever floated as a limited liability concern with the comparatively large capital of £150,000. The original syndicate earned large profits but, while the Buck's Reef proved itself undeniably to be one of the best 'small mine' ventures in Rhodesia, its development and progress never really justified its flotation into a large concern with offices in London and Johannesburg, a head office, engineering staff, and all the organization and administration of a really big mine. Such a policy has been the undoing of more than one Rhodesian venture, and it is now all too evident that the name of the Buck's Reef will have to be added to the list of misjudged mines. The 'profit' for the quarter ended March 31 was only £752 and much of it was eaten up by capital expenditure. In Bulawayo it is freely rumored that the mine is on the eve of closing down.

It is reported that cassiterite has been discovered in the vicinity of Selukwe. The statement as yet lacks confirmation but it is becoming apparent that tinstone occurs widely in Southern Rhodesia. The mineral has already been found in three widely separated areas in Mashonaland, and the present extraordinarily high price obtaining for tin is stimulating search for its ores throughout the whole of South Africa.

### AUSTIN, TEXAS

DEVELOPMENT AT THE HAZEL.—SALE OF THE BONANZA.—NOTES OF PROGRESS.

Good reports of development work in the Van Horn district, west of Alpine, continue to be received. The Hazel M. & M. Co. and the Commissioners' Court of Culberson county have jointly constructed a good wagon-road from Van Horn to the mine, 14 miles. The company has in operation a number of gasoline trucks, carrying in supplies and taking concentrate and the richer ore to the railroad. The first unit of the new 100-ton mill is now being constructed. The Hazel mine has a record of producing \$500,000 worth of ore. Only that which ran 50 oz. silver or better per ton was shipped. This left a dump which is said to contain more than \$100,000 worth of ore that will give an average return of \$15 per ton gross and a net return of \$9 per ton when milled. The company which is now preparing to resume operation of this mine on a large scale is composed of John H. Hughes, W. F. Wright, C. F. Freeman, all of Dallas; Charles A. Cutler, of Houston, and others.

J. F. Johnson, a mining engineer of Parral, Mexico, and associates, recently purchased the old Bonanza mine, situated just west of Sierra Blanca, Texas, the consideration being \$14,000. The ores are zinc and lead sulphides carrying silver. There is a large dump, besides the bodies of underground ores that have been exposed. A good market for the ore, which runs about 45% zinc, has already been established. The railroad shipping point is only two miles from the mine. William Linderburgh recently purchased the Black Shaft and Sancho Panzo mines, situated in the Van Horn district, about two miles south of the Hazel mine, and will construct a mill. Considerable development work has been done upon the Black Shaft, which contains copper and silver ore. The surface workings of the Sancho

Panzo mine have yielded several thousand dollars in copper and silver.

The New Era mine, situated north of Van Horn, is being developed under the direction of S. H. Worrell. Quantities of ore that contain 17% tungstic acid are being taken out. This ore is worth more than \$100 per ton. James Arthur has opened a promising gold prospect six miles from Alpine. He is making preparations to begin regular shipments to the smelter at El Paso. There is much activity in mining prospecting in the mountains around Alpine. In the Shafter district several new claims have been recently located. Preparations are being made for considerable development work in that district during the next several months. The Terlingua quicksilver district, in the southern part of Brewster county, is keeping up its record of production. The sale of several undeveloped cinnabar properties in that section is reported, and it is said the purchasers will start development work some time this fall.

### TORONTO, CANADA

SEARCH FOR GOLD IN THE NORTH.—MILLING AT PORCUPINE.

—PROGRESS AT COBALT.

An expedition organized by A. W. Scott of Toronto, usually known as 'Lucky Scott,' is preparing to leave St. John, Newfoundland, for an 18 months' trip to Baffin island, to search for placer mines. Mr. Scott has had experience in various parts of the globe and made money in Cobalt and Porcupine enterprises. He was for several years a partner of F. Augustus Heinze. Other members of the party are Alexander Gillies and Ernie Holland, well known in connection with Northern Ontario mining, F. Osgoode Pell, New York, Arthur Langdon, and Thomas Morrissey, Nevada placer miners, and Frank Vasser, a South American miner. The expedition is financially backed by J. R. De Lamar, W. B. Thompson, and F. N. P. Pell, of New York. A ship of 300 tons burden has been chartered and will sail from St. John, Newfoundland, about July 10. Its immediate destination will be Ponds inlet, on the northern coast of Baffin island, across from Greenland, and provisions sufficient for two years will be taken. Reports of placer goldfields on Baffin island were brought back by the Government steamer *Arctic* last fall, Robert James, the second officer, having secured rich samples. Mr. James accompanies the Scott expedition as guide and interpreter. The only inhabitants of the country are small bands of Eskimos, and the nearest white settlement is one thousand miles distant.

Four mills are now in regular operation at Porcupine, the Dome with 40 stamps, the Hollinger with 30, the McIntyre with 10, and the Vipond, with a crusher plant and ball-mill, handling only a few tons per day, owing to the non-arrival of a portion of the machinery. No information as to the actual gold production has been given out. The Merrill plant at the Dome is reported to have been found highly effective and satisfactory, the extraction of gold from the ore being almost complete. The second level at the Crown Chartered is proving up well. Driving was done for 36 ft. on the quartz stringers recently found, and a raise cut at the end of the drift enclosed a lens of high-grade ore. Conditions at the 200-ft. level are reported equally as favorable as at 100 ft. where over 900 ft. of underground development shows parallel rich quartz lenses, with intervening schist which carries good ore in some places. At the McEneaney the vein, which was 2 ft. wide at the depth of 200 ft., has widened to 6 ft. on the 300-ft. level, and shows persistent gold content. The company will test 100 tons at the McIntyre mill to decide whether the cyaniding process will be advisable. Another pocket of rich ore has been found at the 50-ft. level of the North Dome. The shaft is being put down to the 100-ft. level, where a cross-cut will be run north to the vein and driving undertaken to explore the orebody. The Porcupine Lake, which is putting down a shaft to 100 ft., discovered gold in the porphyry at the base of the shaft at a depth of 10 ft. At the Plenaurnum driving has been done for 125 ft. on the

vein found in No. 2 shaft, where it carries one foot of good ore. A new vein has come into it, widening the quartz to 3 ft. The McIntyre, on No. 2 vein at 200 ft., has opened a body of ore averaging 66 in. wide, which promises well. The main vein of the Swastika has been cut at the 400-ft. level, where it shows over 5 ft. of quartz carrying free gold. The foundation of the stamp-mill is being constructed. Ten stamps will be erected at first, the number to be increased later if required.

The Whiskey Lake region, on the north shore of Lake Huron, which a few weeks ago was the scene of a short-lived gold rush, has been examined by A. P. Coleman, who reports to the Provincial Department of Mines that of all the claims which have been staked only one, the Peyton, shows any promise. It has an outcrop of quartz carrying free gold, but no well defined veins. A number of low-grade copper deposits have been found in the district.

Cobalt and the adjacent silver-producing districts are showing renewed activity, the industry receiving a decided stimulus from the increased price of silver, and the construction of the Elk Lake branch of the Temiskaming & Northern Ontario railway. A number of abandoned prospects are again being operated, particularly in the outlying districts, where the cost of transportation renders the working of all but the richest deposits unprofitable. In the Elk Lake districts, where only two prospects were being worked a year ago, there are now twenty in active operation, and in Gowganda a similar revival has been experienced. At the Ophir property in Cobalt active work has been in progress for two months, and three veins, carrying good milling ore, have been found in sinking a new shaft. The Buffalo has just broken ground for a refinery capable of handling the whole product of the mine. The process employed at the Nipissing plant, with some modifications, will be employed. The old Cobalt Central, which after having been in litigation for some years, and was acquired by the Pennsylvania Canadian Co., is under development and has a considerable amount of milling ore blocked out. The Beaver's financial statement for the quarter ended May 31 showed a cash balance of \$55,829 on hand. The mill has been running steadily since March 18, the total production being \$43,907, and the net profits \$36,895. At the mine the main shaft is down to 590 ft. and cross-cutting will shortly begin at the 600-ft. level. High-grade ore is being taken out on the 400-ft. level. An interim dividend of 3% was declared.

The Trethewey's financial position on May 31 was as follows: Cash in bank and due from smelters, \$147,221; ore ready for shipment and in transit, \$55,820; total, \$203,041. The net profits for May are roughly estimated at \$20,000. The statement of the Crown Reserve for the first five months of the year shows a gross production of 1,143,142 oz. valued at \$699,847, which after paying royalty, dividends, etc., left a net surplus of \$816,741. The Wettlaufer of South Lorrain is maintaining net earnings of \$24,000 per month, sufficient to meet the dividend requirements of 20% per year. The new mill is complete, the tailing being re-ground in Huntington mills and treated on slime tables, which produce from 1½ to 3 tons of concentrate per week. These latter are a new feature in the Cobalt district, none of the other mills having yet adopted them. The Dominion Safety Explosives Co., organized by Toronto capitalists, will erect a factory in Coleman township, about three miles from Cobalt, for the manufacture of dinitrolite.

Returns made to the Ontario Bureau of Mines for the first three months of 1912 show an increased value for all items of the mineral output as compared with last year, except gold, which declined because of the Porcupine fire. The silver production was 7,439,044 oz., value \$4,092,405, an increase of \$383,861, though the quantity produced was slightly diminished. Cobalt proper produced 7,006,842 oz., South Lorrain, 285,042 oz., and Gowganda, 147,103 oz. Copper was produced to the amount of 2577 tons, value, \$306,799; nickel, 4722 tons, \$1,009,702; and pig iron 116,824 tons, \$1,858,274.

## SALT LAKE CITY, UTAH

COAL SITUATION IN UTAH.—ASPHALT DEPOSITS.—CONSOLIDATED MERCUR REVIVES.

Development of the coal deposits continues to occupy a large part of the attention in Utah mining. The lead of the United States S. R. & M. Co. in this direction is being followed by a number of smaller companies, and the outlook is for the free expenditure of money in coal operations for the next few years, as the recent decision of the Interstate Commerce Commission regarding freight rates on Utah coal has given it a great impetus. For a number of years Utah coal has been practically shut out of Idaho and the Northwest through differential freight rates in favor of Wyoming coals. The Harriman railroads have been interested in the Wyoming fields and have sought to maintain a monopoly for Wyoming coal in the Northwest. In the case of the Castle Valley Coal Co. and Consolidated Fuel Co. versus the Atchison, Topeka & Santa Fé and 25

MAP OF UTAH.

other railroads, the Commission has handed down a decision fixing the differential at not over 25c. per ton on Utah coal to points in Idaho, Montana, Oregon, and Washington. Previously, the differential has been as high as 75c. per ton.

The Pittsburg-Salt Lake Oil Co. has begun a campaign to open a market for Utah rock asphalt. The company owns a deposit of 480 acres near Sunnyside, Carbon county, and recently conducted an excursion of Salt Lake and Ogden city officials and others to the property. Utah asphalt has been used spasmodically in Salt Lake, and the paving has given excellent satisfaction, but the organizations controlling the better established product have been able to keep control of the city contracts through underbidding. The owners of the Utah asphalt have never been properly equipped for getting out the product economically in quantities. It is announced that the Pittsburg-Salt Lake company proposes to equip its quarries thoroughly for economical extraction on a large scale, and will make a systematic effort to go after the Western market.

The Consolidated Mercur, operating one of the pioneer cyanide plants, is certainly dying a lingering death, if death it is to be. Over a year ago the directors officially informed the stockholders that the property was on its last legs, and would have to close down within the year unless new ore-bodies were discovered. But the plant was kept in operation through the year, at a slight profit. Again, before

the time for the last annual meeting, the directors notified the stockholders that they would be asked to vote authority to the board to sell the equipment and close down permanently. The stockholders gave this authority, and now it is announced that new ore has been developed which will keep the old mine and mill going at least another six months. The holders of the shares are now hoping that the property will continue this show of vitality and develop more ore-bodies to prolong this lease of life.

Local shareholders of the Ohio Copper Co. are agitating the formation of a stockholders' protective committee, but as yet nobody has taken the lead to crystallize this feeling. This applies also to bondholders, of whom there are a number in Salt Lake City. Local people have always had a great deal of faith that the Ohio, with proper management and financing, would attain a position profitable to all concerned. The majority still hold to this belief, although they have not taken kindly to the reorganization plan, calling in effect for an assessment of \$1, with liquidation of all stock which does not come into the reorganization on a basis of 25c. per share. Those most familiar with the property would like to see the Heinze interests eliminated, control of the Mascotte adit by the Ohio company, enlargement of the mill, and the expenditure of more money for development of ore. While the new financing plan is supposed to provide for all of these things except the ownership of the Mascotte adit, the local stockholders think ownership of the means of outlet for ores should be included in order to insure permanent success. Apparently this is one point on which Heinze intends to stick out indefinitely, for the Mascotte adit has been a source of great profit to him. Despite all this talk, however, the proposed reorganization plan has been acted on favorably by the stockholders at the adjourned annual meeting at Portland, Maine, and indications are that it will go through unless legal action is taken to prevent it.

### GLOBE, ARIZONA

INSPIRATION VISITED BY OFFICIALS.—MIAMI PRODUCTION AND PROSPECTING.—OLD DOMINION AND SOUTH LIVE OAK.

Charles E. Mills, formerly manager of the mines at Morenci, and who was recently appointed general manager for the Inspiration Con. Copper Co., has arrived in Globe to assume charge of operations at the mine. He was accompanied by W. H. Aldridge, representing the controlling interests in the company; L. D. Ricketts, consulting engineer, and W. D. Thornton, the vice-president. Over 500 men are employed in development and construction work. Sinking of three development shafts continues, also the main west working shaft, which is now over 60 ft. deep. It is intended to sink this shaft 1000 ft. for the extraction of ore from the Live Oak orebody. The new Ingersoll-Rand compressor of 1200-cu. ft. capacity is now in operation at the portal of the Inspiration adit.

Preliminary figures give approximately 2,700,000 lb. as the production of the Miami Copper Co. for June, or about the same as for May. There were mined 89,900 tons of ore during the month. One churn-drill is at work proving the northeastern part of the property, and a Sullivan diamond-drill is in operation on the 570-ft. level exploring the ground below that level. It is reported that ore has been developed nearly 500 ft. below the level, but B. B. Gottsberger, the manager, will neither confirm nor deny the report and states that the future policy will be to make public no more information on results of diamond-drilling.

The Old Dominion smelter produced 2,112,000 lb. of copper in June, with an average of  $2\frac{1}{2}$  furnaces in operation. It is expected that three furnaces will be working in July as the amount of custom ore received is gradually increasing, due to the stimulus of the present high price of copper, and it is probable that the mine production will also be slightly increased. About 1200 men are employed.

Churn-drill hole No. 1 of the South Live Oak Develop-

ment Co. has been discontinued at a depth of 825 ft. without discovering ore. The drill is being moved to another location, where it is proposed to start a new hole on a faulted zone in the granite formation. John Rose reports the discovery of copper ore in a 100-ft. adit in diabase on the Rose group of nine claims north of and adjoining the Inspiration. He states that a vein of copper-silicate ore,  $2\frac{1}{2}$  ft. wide and averaging 15% copper, has just been disclosed. The larger mines of the Miami district are gradually supplanting horses with motor trucks for hauling supplies from Miami to the mines. Inspiration has three trucks, a  $3\frac{1}{2}$ -ton Alco, a 2-ton Velie, and a 1500-lb. Velie. A 3-ton Velie is hauling supplies to the Live Oak mine, and the Miami Copper Co. is using a 1500-lb. Velie.

### BOSTON

UNITED VERDE EXTENSION REORGANIZATION.—BUTTE & SUPERIOR LITIGATION.

The United Verde Extension M. Co. illustrates the futility of announcing a reorganization, and seeking to bolster it with the name of some prominent man. The directors of the company announced a plan of reorganization recently which calls for an increase in the capital stock from 400,000 shares, par \$10, to 1,500,000 shares, par 50c. The company owes \$20,000. It is proposed that new stock be issued in exchange for that now outstanding, on a basis of share for share; that 40,000 shares of treasury stock be issued to liquidate the debt of \$20,000, and that 50,000 shares be sold to James S. Douglas, an Arizona banker, the son of James Douglas, president of Phelps, Dodge & Co., for 50c. per share, realizing \$25,000 in cash for deep development work. Mr. Douglas and his associates, in addition, were to be given an option until June 15, 1915, to purchase all or any part of 400,000 shares at par, 50c. per share. Because of his services in financing the company's affairs, Mr. Douglas, according to this plan, was to receive 150,000 additional shares of stock. When the announcement was made it was apparently so disingenuously worded as to give the idea that the senior James Douglas was to step in as sponsor for this checkered prospect of the Jerome district. It was not until confirmation was sought that it was made plain that he was in no wise concerned in the deal. The fact that his son alone figured in the matter, that the plan of reorganization was not considered equitable, and that due pains were not taken at the outset to disabuse the public of the natural impression that the Phelps-Dodge interests were identified with it, caused the stock to decline, instead of appreciate. A protest is being voiced against the reorganization plan, and there is talk of a protective company of Boston stockholders being formed to present a more acceptable plan of reorganization.

Shares of the United Verde Extension have suffered a good deal in price because of the suggestion that W. A. Clark would institute litigation against the company. A similar case is that of Butte & Superior, which recently suffered an 8 or 9 point decline because of a like menace. Butte & Superior's estate was formerly among the Clark holdings and adjoins the Elm Orlu. Boston market interests were alarmed at the news sent from Butte to the effect that Mr. Clark proposed to start an apex lawsuit against Butte & Superior. The remote possibility of such litigation sent the stock off from the high price of  $51\frac{3}{4}$  it attained a few weeks ago and at the same time sent cold chills up a number of Boston spines. Hayden, Stone & Co. are not believed to be particularly well liked by Mr. Clark, who has more than once given voice to the opinion that the porphyry copper producers have not acted in good faith under the curtailment agreement of two years ago. Hayden, Stone & Co. have resented Mr. Clark's attitude, but when it became definitely known that Mr. Clark intended to fight Butte & Superior, that banking house suggested that the matter be turned over to a disinterested body of engineers to settle by arbitration. It appears probable that this will be done.

## General Mining News

### ALASKA

#### CORDOVA

The Hubbard-Elliott Copper Co. has arranged for packing in 20,000 lb. of provisions this summer. Sixteen men are at work on the 'Albert Johnston' adit, which must be driven 900 ft. to intersect the lode. It is hoped to complete the work in May 1913. It is said that this will make available 694,000 tons of ore averaging 20% copper, but the name of the engineer making the estimate is not given. The Regam M. Co. is working 15 men on a copper property near Kennicott; E. F. Gray is directing the work. Stephen Birch is quoted as estimating shipments from Kennicott this year at 40,000,000 lb. copper, as against 23,000,000 lb. in 1911.

#### JUNEAU

The report of the Alaska United G. M. Co. for May shows that 18,634 tons of ore was crushed from the Ready Bullion and 20,790 from the 700 Ft. Claim, realizing \$50,232 and \$48,820, respectively. The yield per ton of ore in the former was \$2.72, and the operating profit \$22,222; in the latter, \$2.37 per ton, yielding profits of \$22,467. On the Ready Bullion 296 ft. of development work was done; on the 700 Ft. 538 ft. At the Alaska Mexican 20,517 tons was crushed, yielding \$2.98 per ton, at an operating profit of \$30,965. During the month 147 ft. of development work was done.

Small acetylene lamps, worn on the cap like a coal-miners' lamp, are being substituted for candles in the Treadwell mines.

#### KATALLA

The Amalgamated Development Co. has increased the capacity of its refinery to 800 gal. per day. Ore has been found at 580 ft. in an additional well, but drilling is being continued. A rotary drill has been ordered. The Alaska Oil Fields Co. and the Royal company have each ordered rigs for drilling.

#### NOME

Six new dredges are expected this year, two for the Port Clarence district, two for Casadepaga creek, and two for the Kotzebue country. The New Era Mining Co. has been organized locally to buy the two stamp-mills here and move them to Snow gulch.

#### VALDEZ

A steam-hoist has been ordered for the Alice property on Shoup bay. The surface tram, 900 ft. long, at the Fidalgo mine, has been completed, but the aerial tram will not be ready for operation for about three months.

### ARIZONA

Much protest is being made among mining men against the new tax schedule. Following the creation of a tax commission and the adoption of tax laws by the last legislature, the assessed valuation of mining property has been raised about 300%. In Yavapai county the assessment was raised from \$1,600,000 to \$5,200,000, and in Cochise county from \$4,000,000 to \$12,000,000. Probably a hearing before the commission will be requested.

#### COCHISE COUNTY

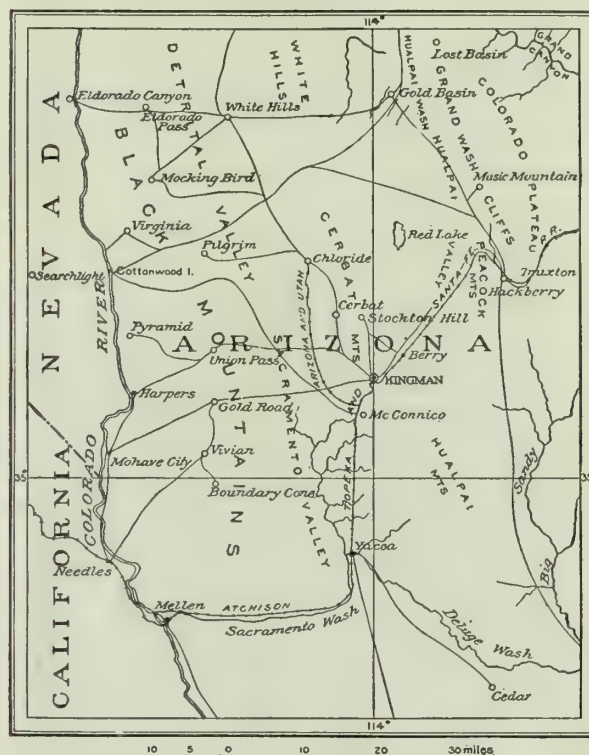

The Mascot Copper Co. is prospecting its property near Dos Cabezas with diamond-drills under the direction of F. L. Sizer. It is now announced that in one hole at a depth of 600 ft. a body of sulphide ore of good commercial grade, 44 ft. thick, of which 33 is high grade, has been penetrated in territory not previously prospected. Mr. Sizer believes that the same lens of ore has been found at two other places.

The Huachuca mine, consisting of 160 acres of patented mineral land near Hereford, has been sold to J. J. Brown and F. W. Graham, of Denver, by Mrs. J. H. Hockley, and the first payment of \$5000 has been made. Under the terms of the bond the new owners agree to spend \$20,000

on the property during the year. The erection of a mill is planned. The Minneapolis Copper Co. has resumed operation and will ship 50 tons of high-grade ore weekly to the Douglas smelter. The C. & A. mine, near Courtland, has resumed work. Ore shipments from Courtland for the six months ended June 30 amounted to 460 cars of 45 tons each, while the total shipments in 1911 were only 462 cars.

#### MARICOPA COUNTY

The Rogers Spring M. & S. Co. smelter at Rogers Spring, 35 miles northeast of Phoenix, is expected to blow in on September 1. The capacity of the plant is 60 tons per day, and a large supply of custom ore is available. Coke will have to be hauled from Phoenix. It is reported that the Harqua Hala mine will be reopened early in July. Robert Browne has purchased the buildings of the Goddard mine. An orebody 6 ft. wide has been found in the Mildred mine, near Stanton; some of the assays run as high as \$100 per ton. D. B. Genung is superintendent.

WESTERN ARIZONA.

The Nelson group, in the San Domingo district, has been sold, and a mill will be built by the new owners. The new mill at the Monarch is expected to be in operation shortly. Large bodies of sulphide ore have been found in the Vulture mine.

#### MOHAVE COUNTY

Thomas McNeely has bonded his property in Mineral Park basin to H. E. Bierce, who is driving a deep adit to cross-cut the vein. The Frisco mines have produced a bar worth \$7000 from a two-weeks clean-up. E. H. Barton is manager.

Machinery for the 200-ton mill of the Arizona South-western M. Co. has been delivered at the property and it is reported that the mill will be in operation within three months. L. Hoffinan is general manager. At the Mitchell 35 men are at work sinking the shaft to the 500-ft. level. The shaft is in ore which is reported to average \$100 per ton. Joe Onelto is in charge.

#### PINAL COUNTY

The Calumet Copper Creek M. Co., 35 miles from Hayden, has erected a 150-ton mill, 2½ miles from the mine, and is hauling the ore with auto trucks. About 75 men are employed and high-grade ore is being shipped to the

El Paso smelter. R. Sibley is president and general manager.

The Geeseman-Leatherwood property has been closed down by the Copper Queen Co. and will be allowed to lie idle until a branch railroad can be extended to it. There are large high-grade orebodies in the mine, but they cannot be worked at a profit with the present 70-mile wagon haul required.

#### YUMA COUNTY

The Swansea Con. M. Co. has arranged to exchange ores with the Blue Bell, as this will give a better smelting charge at both the Humboldt and Swansea smelters, and four carloads per week are thus being exchanged. Reports from Swansea are that the smelter will soon be blown in. C. Clerc is manager. The Steece mine has been closed down for the summer. The Corem M. & R. Co. has taken over the Henry Roberts and Burke Bros. property in the Riverside mountains. A. L. Engedow is superintendent.

### CALIFORNIA

#### INYO COUNTY

The Poverty mine, which was bought by A. Baring Gould from the Melton estate, has resumed work. Extensive improvements are being made, two shifts are at work, and the mill is in steady operation. The main shaft at the Custer has reached a depth of 230 ft. John Thorndike is manager. The Christmas Gift is shipping ore averaging \$80 per ton; 500 tons is ready in the stopes. L. D. Skinner is manager. Work will be resumed at the Lucky Jim, under the management of Chas. Collins. C. M. Long has bonded his claim, adjoining the Custer, to Mr. Minear for \$8000. The Cerro Gordo is making regular shipments of zinc ore to the smelters in Oklahoma. C. J. Borglin has set up a dry washer in the Stringer district. A 15-hp. engine has been installed on the claim of the Gold Placer Mining Company.

#### MODOC COUNTY

The reported placer strikes on Dry creek, west of Goose lake, have proved to be unfounded. Twenty tons of ore has been shipped from the Sunshine mine to the Selby smelter. Development work is in progress and the erection of machinery is planned. F. L. Schrott and R. L. Mack, who have a lease on the Yellow Jacket claim, are reported to have discovered a 20-in. vein of rich ore. The Eureka Milling & Amalgamating Co. has been incorporated for \$50,000 by F. L. Evans, F. O. McFall, and M. B. Rice to construct a custom milling plant on the Del Floy claim.

#### NEVADA COUNTY

The water supply in the upper Lake region is now so short that all mining operations will soon be compelled to suspend. Rich ore has been found on the 400-ft. level of the Mountaineer mine, owned by P. and J. Bender and F. J. Sloat. At the Red Top rich telluride ore has been found, a lot of 30 tons averaging \$32 per ton. F. A. Smith, the manager, is negotiating the purchase of a 5-stamp mill. A. C. Travis has discovered a Tertiary river channel  $\frac{1}{2}$  mile east of Graniteville and has organized the Graniteville G. M. Co. to develop it. Attachments totaling \$25,000 have been placed upon the Balsam Flat mines, owned by the Alleghany M. Co., by W. Hatch and G. A. Roberts. Permission has been granted to the Pacific Gas Light & Electric Co. to erect two power plants on the Bear river.

#### SHASTA COUNTY

The Victor Power & Mining Co. has secured a court order permitting it to make an underground survey of the Midas, at Harrison gulch, which it claims is trespassing on the Victor ground at the 1200-ft. level. The Farmers' Protective Association is still anxious to take steps to force the Mammoth smelter to cease operations, but has so far been unable to raise funds for litigation.

#### SIERRA COUNTY

(Special Correspondence.)—The gravel channel at the Monte Cristo has been recovered. At point of intersection

fair gold content is reported. The Croesus Mining Co. is laying a line of 3-ft. wooden pipe to convey water to mine and mill. The 20-stamp mill has been overhauled. C. W. McMeekin is manager. New machinery has been installed at the Sixteen-to-One and development has commenced. Mark N. Alling and W. J. Belcher have given a short-term bond and option on their Golden Bear claims to P. H. Darrah, of Pomona. The claims are between the Orient and Snowden Hill mines and fair-grade gravel has been found. Charles W. Morse has taken over the Oxford mine, near Downieville. It is reported that the Brown Bear, near Downieville, will be equipped with a steam-power plant this summer; J. G. Jackson is operating the mine under bond. The Oasis M. & M. Co. has arranged to operate the Kenton mine and mill with electric power. The Rio Antigua Mining Co., owning the South Fork quartz and gravel claims at Forest, is being reorganized as the South Fork Mines Co. The company recently acquired the properties, after operating for several years under bond and lease. It is planned to develop the quartz veins disclosed while driving for the gravel channel. F. W. Kuhfeld is superintendent. Arrangements have been made for the extensive development of the Uncle Sam mine, near Forest. A 30-ft. body of quartz has been found 2000 ft. from the adit portal, with shoots of ore showing. The vein is considered a north extension of Alleghany orebodies. G. P. Stone is manager.

Downieville, July 8.

#### SOLANO COUNTY

The suit against the Selby smelter, by the Supervisors of Solano county, is expected to come up for its next hearing by the middle of August. T. C. Gregory has been engaged as assistant counsel for the plaintiffs.

#### YUBA COUNTY

J. J. Cusick, president of the Yuba Gold Mines Co., has been sued by Mrs. Jennie E. Robinson of Chicago for \$30,000 for the return of money obtained by fraudulent representations. Much interest is being created by the purchases of land made by Newton Cleaveland, but it has not been made public in whose interest Mr. Cleaveland is acting.

### COLORADO

#### CLEAR CREEK COUNTY

An electric pump is being installed at the Smuggler mine, where B. C. Catren is manager. At the Big Indian mine on Leavenworth mountain driving is in progress, and the indications are encouraging. Hummer & Herber are breaking a large tonnage of smelting ore in the Capital mine, and Moscript & Brandstetter are breaking a fair tonnage of ore.

#### GILPIN COUNTY

The Golden Rod, which owns 12 patented claims and two millsites at the head of Silver creek, will use machine drills in extending its adit, which is in 800 ft. Some promising veins have already been cut, and the adit will be extended 250 to 300 ft. A. Waters and John Hutchens, operating the East Missouri mine on Quartz hill, are taking out good ore from the 150-ft. level. A shipment of three tons of smelting ore recently gave returns of 3.24 oz. gold and 5 oz. silver per ton. A recent trial shipment from the Bates mine gave returns of  $2\frac{1}{2}$  oz. gold and 20 oz. silver per ton. At the Oliver mill in Chase gulch, 25 stamps are dropping. Nels Olsen and John Swanson will install a gasoline hoist on the Cicero, in Chase gulch.

#### SAN JUAN COUNTY

The road to Animas Forks has been opened and trains are now running to the Gold Prince mill. A new mill will be constructed at the Bagley adit and the framed timber is being shipped to the site. The 5-stamp mill of the Intersection is being increased to 10. A 3-ft. vein of rich ore has been uncovered in the Esmeralda, in Minnie gulch, a sample across the face giving assays as high as \$1500 per ton. During June the Highland Mary shipped 300

tons of ore, averaging over \$80 per ton, to the smelter at Durango. The Shenandoah, in Cunningham gulch, will resume work soon. The Brooklyn mine, on Red mountain, has shipped two cars of ore.

TELLER COUNTY (CRIPPLE CREEK)

The ore treated by the mills of the Cripple Creek district is estimated as follows by the Cripple Creek Times:

	Tons.	Av. Val.	Total.
Golden Cycle .....	32,000	\$20.00	\$ 640,000.00
Portland .....	10,000	22.00	220,000.00
Smelters .....	3,850	65.00	250,250.00
New Portland .....	13,960	3.51	84,999.60
Stratton's Independence...	10,808	2.86	30,910.88
Kavanaugh .....	1,400	2.00	2,800.00
Wild Horse .....	800	4.20	3,360.00
Total .....	72,818		\$1,186,320.48

The May production was 76,800 tons of a value of \$1,263,344. The Elkton Consolidated made a record production during the month with an output of 3000 tons of \$20 ore. The El Paso produced 67 cars of \$30 ore on company account, and 40 cars of \$20 ore was shipped by lessees. The boiler for the new plant at the Nicholls shaft has been installed. Electric hoists have been installed on the April Fool claim on Squaw mountain and on the Lexington Gold Hill. The Merrimac Con. Mines Co. has been reorganized. The Little Frank S. M. Co. has been sold under writ of execution to Walter A. Dorland for \$9767. The properties of the Cable Con. G. M. Co. have been sold by the sheriff to Olive Granfield for \$3795. Suit has been brought by the Roxana G. M. Co. against the Doctor-Jack Pot Mines Co. for the alleged unlawful extraction of ore valued at \$1,000,000, on the ground that the apex of the vein from which the ore was mined lies in the Mountain Monarch, adjoining the Lucky Corner on Raven hill. In the suit between the Doctor-Jack Pot and the Work M. & M. Co. the court decided that this vein apexed on the Lucky Corner, so the litigation seems likely to be long and costly.

IDAHO

BLAINE COUNTY

It is proposed to consolidate the Bullion, Mayflower, and other mines at Bullion, with the Point Lookout group, the Quincy Junior interests, and others, for the purpose of driving an adit to drain and develop all the claims west of the main road in Bullion gulch. Frank Henderson and C. C. Todhunter have been examining the properties.

IDAHO COUNTY

Sale of the Coeur d'Alene group of claims, in the Ten-Mile district, is reported. Peter Proulx is the vendor. A prospect shaft is being sunk on the Mineral Zone group, recently sold to J. R. Painter. Arthur Hillier is in charge of the mine.

SHOSHONE COUNTY

The 150-ton mill at the Black Horse has begun operation. The Amazon-Dixie M. Co. has a new water-driven air-compressor and an electric lighting plant. Wesley Everett is in charge of the property. The Iron Mountain Tunnel Co. has raised \$65,000 for development purposes, and it is planned to resume mining and milling operations by September 1. The Gold Hill M. Co. has nearly completed its 10-stamp mill and crushing is expected to start August 10. The ore is said to average \$17.20 per ton. It is reported that the Stewart M. Co. has over \$150,000 in the treasury, a loan of \$84,000 to the Ohio Copper Co. having been recently repaid.

The Bunker Hill & Sullivan has brought suit against the Caledonia, in order to fix boundary lines and quiet the title to a portion of the ground. The Bunker Hill claims the orebodies below the 500-ft. level and has enjoined the Caledonia from working them. At the meeting of the Bear Top-Orofino M. Co., held July 1, a new company, the Twin Star Mining Co., was incorporated to take over

the Bear Top. The new company will assume all indebtedness and will issue shares to the stockholders in the other companies upon a 90% basis. It is expected to resume operation by the middle of July, and the lower adit, now in 100 ft., will be continued to a length of 2600 ft. The third payment has been made upon the Tuscumbia and a contract has been let to drive a 300-ft. adit.

WASHINGTON COUNTY

The Landor Copper Co. is shipping ore that averages 30% copper, in earload lots, according to the Wallace Miner. Several of the Eastern stockholders have recently visited the mine and the report has been given out that the equipment will be increased and the scale of working enlarged.

MONTANA

SILVERBOW COUNTY

(Special Correspondence.)—A private telegram received in Butte states that after a conference with W. A. Clark,

SMELTER, GREAT FALLS.

who was hurriedly called to New York, a settlement has been brought about wherein it has been agreed that Mr. Clark will drop his contemplated suit against the Butte & Superior Co. for the alleged extraction of ore from the Elm Orlu mine. It cannot be learned just how much ore it is alleged the Butte & Superior people have taken from the Clark mine, which adjoins the Black Rock, but according to reports it is said that the Clark engineers claim that there has been a very large amount.

Butte, July 6.

The copper output in Butte for June was 24,607,582 lb., or 4,474,780 lb. less than in May. The decline was due to the fact that there were only 29 working days and because the Butte Coalition mines were out of commission on account of changing the hoist from steam to compressed air for power. The Tuolumne output was less on account of mining lower-grade ore. The output in June, 1911, was 20,412,120 pounds.

The mining companies and the miners' unions have signed a 3-year contract providing that the minimum wage shall be \$3.50 underground and \$3 for surface work. When copper sells between 15 and 17c. per pound these shall be increased to \$3.75 and \$3.25. When copper is over 17c. underground men will receive \$4 and when over 18c. surface workmen will receive \$3.50. The Lincoln Trust Co., of

New York, has begun suit to foreclose a mortgage of \$2,000,000 on the La France Copper Co. The Lexington Mines Co. has been formed to bid in the La France, and it is reported that the United Copper Co. of which the La France is a subsidiary, will be reorganized. About one-third of the \$45,000,000 shares of this company are held abroad, largely in Holland, and a representative of these interests is now in this country to bring about the reorganization. The Butte & Superior mill is working at full capacity, making a 92% recovery. A large orebody has been found on the 1200-ft. level.

## NEVADA

### CHURCHILL COUNTY

Two cars of concentrate from the Nevada Hills has been shipped to the International smelter at Tooele, with which a contract has been signed. Shipments are said to average 600 oz. silver per ton. The mill of the Nevada Hills is now working at a high efficiency. Reports have been received of the discovery of copper deposits about 100 miles south of Winnemucca, and 18 miles from Boyer's ranch, in Dixie valley. Some of the ore is reported to contain 30% copper and the amount of 3% ore is reported very large.

### ESMERALDA COUNTY

The production of the Goldfield Consolidated Mines Co. in June, according to the preliminary estimates prepared by J. F. Thorn was 32,360 tons, the largest tonnage for any single month in the history of the company. This includes ore that has been extracted from the deepest workings of the Clermont and Grizzly Bear mines, at depths of 1000 and 1300 ft., and that has been shipped to the reduction plant of the International Smelting & Refining Co. at Tooele, Utah. Gross recovery of gold from the June production is placed at \$542,000, operating expenses at \$200,000 and net realization is estimated at \$342,000. This shows a gross value of the product to be slightly less than in May, but the net profit is larger than in the previous month. The tonnage produced during the month is more than 2000 tons in excess of the largest output made in any month in the past. It is probable that the final report for the month will show that the high-grade ore shipped to the smelter has increased the profit during June.

### LYON COUNTY

Large orebodies are being developed below the fourth level of the Mason Valley mine, the average being  $4\frac{1}{2}\%$  copper. Development work at the New Yerington Copper Co. property is planned and the drifts on the 250, 300, and 400-ft. levels will be extended. Good ore is being found on the seventh level of the Nevada Douglas; the vein is 20 ft. wide. The inclined shaft is being deepened 200 ft. It is reported that the Mason Valley will take over the Bluestone mine. The Bluestone, which is owned by J. R. De Lamar, has been developed to a depth of 350 ft.; drilling to a depth of 700 ft. has shown that the ore is low grade. It is reported that 1,500,000 tons of 2% ore is developed.

### NYE COUNTY

A fire at Tonopah on July 8 did \$150,000 damage to the town, but none of the mines are affected. Rich ore is reported at the Toro Blanco, at Manhattan; F. H. Mitchell is manager. Much interest has been excited at Tonopah by the discovery in the Merger Mines property. The shaft has reached a depth of 970 ft. and has passed through 30 ft. of vein material, of which 12 ft. averaged \$25 per ton. The Mizpah Extension is raising from the 500-ft. level in \$40 ore. The Jim Butler will utilize the old Belmont mill. Eight mines are now producing in the district and 24 hoists are in operation. The new Belmont mill started work on July 7. The summary of operation of this company for the quarter ended May 31 is as follows:

Receipts from sales of ore, bullion, etc., \$855,849; mining, milling, and administration expenses, \$450,826; net earnings for quarter, \$450,023; miscellaneous income, \$9118; total net income for the quarter, \$414,141. Available resources, May 31, 1912: Due from smelters, \$167,830; due from

others, \$5020; loans on collateral, \$150,000; cash in banks, \$789,006; total, \$1,111,857.

The annual report of the West End Consolidated shows that during the year ended March 31, 15,903 tons, averaging \$16.75 per ton was milled at a cost of \$6.30 per ton, giving a total net return of \$158,387. Smelting ore, of an average value of \$33.07 was shipped to the amount of 1151 tons, with a net return of \$26,254. Of tailing, 15,905 tons was milled, with a net return of \$2.30 per ton from tailing averaging \$8.70. The total net earnings for the year were \$91,995.

The mines of the Tonopah district shipped a total of 8777 tons of ore, of an estimated value of \$219,425, to the mills last week. The Tonopah Mining Co. sent 3500 tons, the Belmont 1950 tons, Montana 1030 tons, Tonopah Extension 1078 tons, West End 750 tons, and MacNamara 469 tons.

### WHITE PINE COUNTY

Eight men were killed in the Copper Flat pit of the Nevada Consolidated on July 7, by the premature explosion of the powder in a churn-drill hole, one of them being the powder man. The cause of the explosion is not known. There are 750 men employed in the open cuts, 300 at the Veteran, and 250 at the Giroux mines. The Giroux is shipping ore from the Taylor dump, where 600 tons of high-grade ore is piled up. It is expected that work will shortly be resumed on the 1200-ft. level of the Alpha workings. Shipments during the past month have averaged over 1000 tons per day. The contact deposits in the Veteran are holding out surprisingly well and are creating greater faith in their possibilities as to persistence and extent. The Copper-mines company is shipping ore of a copper content of 13 to 15%. The Berry Creek M. Co. has been incorporated, with head offices at McGill.

The Railroad Valley Saline Co. has been reorganized into the Railroad Valley Co., of 1,000,000 shares, of which 400,000 will be used to take over the Saline company and 200,000 will be sold.

## NEW MEXICO

### GRANT COUNTY

The Mineral Mountain M. Co. will begin work within the next two months and continue the adit already started until it cuts the vein. The National G. & S. M. Co. has opened a 4-ft. vein of good ore. At the El Oro rich ore is being extracted. George Ingham is in charge and will let a contract to deepen the shaft to 100 feet.

### SIERRA COUNTY

Copper claims near the Victoria Chief have been bonded to El Paso people by Emory Hiccock, but the price has not been disclosed. Some of the best claims of the Caballero district have been optioned by Wilbur Grant and J. C. Tandy, of El Paso. Ore from the St. Lawrence is being hauled to Cutter and accumulated on the dumps.

## OREGON

### BAKER COUNTY

At the annual shareholders meeting of the Humboldt Con. Gold Mines Co., F. R. Mellis was elected president for 1912, and J. A. Howard, secretary. The Laclede Con. Gold & Copper M. Co. is developing a quartz property near North Powder; an adit is being driven and has cut a vein 8 ft. wide. J. A. Gyllenberg is superintendent. Emil Melzer will take charge of the new construction planned for the Blue Mountain M. Co., operating the Last Chance and Baby McKee properties in Cable Cove.

### JACKSON COUNTY

Mike Womack reports the finding of a large orebody on Frog creek, 7 miles from Ashland. Assay returns of from \$4 to \$18 per ton are reported, and it is stated that outcrops of the vein can be traced for several miles. Capital has already been proved for the sinking of a shaft.

### JOSEPHINE COUNTY

The Darkes mine, near the Takilma, has been purchased

by E. E. Phillips. It is expected to begin shipment soon and the ore will be hauled by teams to Grants Pass. Ore assaying \$35 per ton is being taken from the Red Bean mine, on Slaveout creek, owned by Riggs, Flamm & Evans. R. S. Tucker has been appointed receiver for the Alameda Consolidated Mines Co., which owns 800 acres of land and has sold \$13,000,000 worth of stock.

UTAH

JUAB COUNTY

The Eureka Hill Mining Co. has filed suit against the Bullion Beck for \$18,750 for trespass. Directors of the Tintic Standard have levied an assessment of 1/2c. per share. Work on the 1000-ft. level of the Opohongo is in progress. The zinc ore being shipped from the May Day averages \$30 per ton, and it is expected that a considerable profit can be made from this class of ore. The Eagle & Blue Bell is making large shipments from the 700-ft. level. The earnings for May were \$10,000, and those of June nearly as much. The Chief Consolidated now has a surplus of over \$130,000. The Iron Blossom has \$300,000 in its treasury and will pay a dividend this month.

SUMMIT COUNTY

Ore shipments from Park City during the month of June amounted to 196 cars aggregating 7182 tons, 2043 being shipped over the Rio Grande and 5139 over the Union Pacific. The shippers were: Daly West, 2574 tons; Silver King Coalition, 1976; Daly-Judge, 1707; Grasselli company, 290; New York Bonanza, 174; Ontario lessees, 119; Charley Moore, 70; Little Bell company, 143; E. J. Beggs, 72, and Park City Sampler, 42 tons.

The Utah Ore Sampling Co., of which A. W. Gates is manager, has bought the McIntosh ore sampler at Park City. The Utah company, of which Jesse Knight is president, was formed some time ago to take over the Taylor & Brunton sampler at Murray, the Pioneer sampler at Sandy, and the Silver City mill at Tintic. It is reported that the Silver King Coalition may be sold to the consolidated company to terminate the litigation between them. Work has been resumed at the Ontario mill.

WASHINGTON

FERRY COUNTY

During April shipments of ore from the mines of the Republic district amounted to 3077 tons, as follows: Republic Mines Corporation, 2433 tons; San Poil Con. company, 360; Knob Hill, 248, and Rathfon Reduction Works, 35 tons.

CANADA

BRITISH COLUMBIA

The British Columbia Copper Co. produced 996,000 lb. of copper during June. It is reported that a 7-ft. vein of chalcopryite averaging 18% copper has been cut in the shaft of the Rocher de Boule company. The Silver Standard reports that in sinking its shaft 135 ft. silver-lead ore worth \$25,000 was extracted.

It is stated on good authority that the Red Cliff Mining Co., Ltd., will take up the option on a controlling interest in the stock of the Tye Copper Co., Ltd., which expires July 31. The mining company is ready to guarantee delivery of ore at the rate of 100 tons per day at \$1.15 per ton on shipboard. Several of the British shareholders have recently visited the mine. The Salmon-Bear River Mining Co., which has its headquarters in Vancouver, is incorporated for \$1,000,000 in 25c. shares. Of these, 260,000 have been sold for development purposes, and 2,440,000 will be used in a proposed pooling agreement. The company owns eight claims on Salmon river upon which development is in progress. Silver-lead ore has been found in a number of places, and is now being developed.

ONTARIO

The Vipond mill is treating 75 to 85 tons of ore per day and stoping between the 100 and 200-ft. levels is in progress. The stamp-mill of the McIntyre is at work;

good ore is being found on the 300-ft. level, where the drift is in 300 ft. on the vein. A new company has been organized to operate the mill on the Nova Scotia. D. M. Steindler is president. During May the Buffalo mill produced 109,295 oz. of silver from 4553 tons of ore of an average silver content of 28.22 oz. A new vein has been found on the 150-ft. level of the Hudson's Bay mine, where the mill is now treating 70 tons of ore per day. The La Rose Consolidated will pay a 2 1/2% dividend on July 20, making the total for this year 7%. The total dividends paid by this company amount to \$2,954,185. Exploratory work in the Keewatin on the 200-ft. level of the Coniagas has so far been devoid of results, and the vein which was followed on the first level for 150 ft. has not been picked up. Brush fires have been raging at Porcupine, but have done no damage aside from the destruction of cordwood. The new power-plant at the Hughes is in successful operation and shaft-sinking has been started. The Dome mine is reported to have reached a capacity of 10 tons per stamp per day. The Dome mill is crushing 8 tons per stamp per day, and the tonnage could be increased except that it would lead to scouring of the plates. The Hollinger has 20 stamps dropping.

Cobalt shows a steady increase in bullion shipments with an accompanying diminution in consignments of ore, with the Nipissing well in the lead. The total bullion shipments for the year up to June 7 were 2,146,778 oz., of the value of \$1,250,146, the ore shipments being 8577 tons.

MEXICO

SONORA

Five cars of ore have been shipped from the Abundancia to the smelter at Douglas and showed 5 to 17% copper. O. L. Neer and others have the property in bond and lease, and are planning the construction of a narrow road to simplify the freighting problem. The Tucabe mine, 50 miles east of Magdalena, has been sold to an American company for \$150,000, it is reported.

High-graders who have been shipping ore from the El Tigre district to the United States have been detected and the shipments captured. The ore is supposed to have come from the Cinco de Mayo and adjoining mines. The El Tigre mine is making the largest output of its history. W. L. Rynerson has taken a lease of the El Temblor. Work has been resumed on the North Tigre by R. L. Brown.

In a report mailed to the stockholders of the Lucky Tiger-Combination G. M. Co., May 25, it was shown that the net profits from the operation of the mine for the first four months of this year were approximately \$45,000 per month. The net profit for the month of May shows a material increase, being approximately \$75,000, of which \$37,000 was derived from the operation of the cyanide plant, which is now meeting the fullest expectations. The results of operations for the month of May were as follows:

	Tons.	
Crude ore concentrated .....	6183	
Tailing cyanided .....	7728	
Estimated value of shipping ore.....	125	\$ 30,000
Estimated value of concentrate.....	280	64,200
Est. value of bullion from cyanide plant..		70,400
		<hr/>
Total value of May production.....		\$164,600
Less expenses, including cost of mining, milling, marketing, and general expense, but not including depreciation .....		87,000
		<hr/>
		\$ 77,600
Less Kansas City general expense and interest on bonds .....		2,600
		<hr/>
Net profit for May 1912.....		\$ 75,000

Considerable high-grade shipping ore has been discovered on the fourth level of the Sooy vein. At the regular monthly meeting of the directors held on June 20 it was resolved that from this date dividends be declared monthly as the earnings may justify.

## Personal.

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

D. C. JACKLING is at Butte.  
W. C. OREM has gone East.  
J. F. NEWSOM is at Iditarod.  
W. R. BASSICK has gone East.  
ROY L. MACK is at High Grade.  
L. LINDSAY has returned to San Francisco.  
T. LANE CARTER, of Chicago, is in Montana.  
F. LYNWOOD GARRISON is in San Francisco.  
E. P. MATHEWSON has returned to Anaconda.  
E. H. CLARK was in San Francisco this week.  
A. P. ROGERS was in San Francisco this week.  
F. H. BOSTWICK is in San Francisco this week.  
J. J. COLLINS is in London from North Nigeria.  
D. D. MUIR, JR., left for Seattle for Juneau, July 8.  
W. E. SIMPSON is at Fundicion de Los Arcos, Mexico.  
P. N. MOORE has gone to the Yosemite and Los Angeles.  
G. I. ADAMS will sail for China on the *Tenyo Maru* today.  
C. M. EYE was in San Francisco and has left for Mexico.  
C. H. MACNUTT is in London, having left Antofagasta, Chile.

HENRY B. KAEDING will be in New York for several weeks.

H. V. WINCHELL will sail for Europe July 24, returning in October.

GEORGE M. RYALL is in Mexico, but is expected in Los Angeles soon.

L. D. GODSHALL was in Kingman, Arizona, recently and has gone East.

E. P. JENNINGS has returned to Salt Lake City from a visit to the East.

C. T. NICHOLSON is studying the dredging districts of the Yukon and Alaska.

J. A. AGNEW has resigned from the service of Bewick, Moreing & Company.

J. F. KEMP has been elected a member of the American Philosophical Society.

COURTENAY DE KALB is inspecting properties along the west coast of Mexico.

M. W. VON BERNEWITZ sailed from Auckland for San Francisco on July 5.

BAILEY WILLIS has returned from Buenos Ayres and is at Washington, D. C.

JOHN McDONALD has resigned the management of the McEneany mine, at Poreupine.

WILLIAM BREWER was in San Francisco this week, but leaves Victoria the last of the month for Seward, Alaska.

CHARLES O'CONNELL has resigned as manager of the Trethewey mine. HORACE G. YOUNG is now manager.

R. T. HILL was in San Francisco on his way to Los Angeles, which is to be his headquarters for the present.

F. R. HULL has resigned as superintendent for the Empire Mines Co., and will be succeeded by E. S. SHEFFIELD.

R. H. ELLIOT was recently married and has gone to Telluride to be superintendent for the Liberty Bell G. M. Company.

## Obituary

GEORGE M. HILL died at his home in Alameda on July 10 at the age of 46. A mining engineer, he had been for some years interested in real estate, and recently had served with distinction on the Board of Harbor Commissioners of San Francisco.

## Market Reports

### LOCAL METAL PRICES

San Francisco July 11.

Antimony.....	11-11½c	Quicksilver (flask).....	43

Metal Mining in Missouri

The value of the mine output of silver, copper, lead, and

zinc in Missouri for the calendar year 1911, according to J. P. Dunlop, of the United States Geological Survey, was \$30,171,311, compared with \$28,086,887 in 1910, an increase of over \$2,000,000.

a In calculating the metal content of the ores from assays, allowance has been made for smelting losses in case of zinc, but not in the case of lead. In comparing the values of ore and metal it should be borne in mind that the value given for the ore is that actually received by the producer, whereas the value of the metal is calculated from the average daily quotations at New York and St. Louis.

a Including also the small production of lead and zinc ores in central Missouri.

TENOR OF CRUDE LEAD ORE AND CONCENTRATE, SOUTHEAST MISSOURI

	1910	1911
Total crude lead ore.....short tons..	3,693,523	3,974,712
Lead concentrates in crude ore.....per cent..	5.7	5.5
Lead content in crude ore.....do.....	3.5	3.7
Average lead content of lead concentrates.....do.....	62.3	67.3
Average value per ton of lead concentrates.....do.....	\$44.35	\$46.94

The production of silver amounted to 49,867 fine ounces, valued at \$26,430, an increase of 16,771 oz. over 1910. The production of copper was 640,411 lb., compared with 94,452 lb. in 1910. The quantity of lead concentrate produced increased from 248,058 to 258,240 short tons and the metal content of the lead concentrate increased from 161,016 to 178,868 tons. The low prices paid for zinc concentrate during the first 10 months of 1911 caused a decline in the production of zinc. The output of sphalerite was 217,812 short tons, compared with 232,341 tons in 1910. The production of zinc carbonate and zinc silicate concentrates was only 20,119 tons, which was less than in any year since 1907.

There was an increase in ore mined in the southeast Missouri lead district. In the Joplin region the 'soft ground' mines produced about the same quantity of ore in 1911 as in 1910, but the output of the 'sheet ground' mines was about 800,000 tons less. A large amount of development was done in the Joplin region, and the high prices offered for zinc concentrate during the past two months of 1911, though too late to have much effect on the year's production, will probably cause much larger shipments in 1912. The production of silver, copper, lead, and zinc in Missouri in 1911 is shown in the following table:

PRODUCTION OF SILVER AND COPPER IN MISSOURI, 1910-11

Year.	Copper.		Silver.		Lead concentrate, silver bearing, short tons....
	Quantity, lb..	Value .....	Quantity, fine oz. ....	Value .....	
1910 .....	94,452	\$11,955	33,096	\$17,872	35,002
1911 .....	640,411	80,051	49,867	26,430	51,109

In the foregoing tables showing the crude (or 'dirt') and concentrate from Missouri the ores of different nature have been segregated. For instance, the disseminated lead ore of southeast Missouri differs radically from the lead and zinc ores of the so-called 'soft ground' deposits of southwest Missouri, and these in turn differ from the 'sheet ground' deposits of the same region. Each class of ore has its peculiar problems of mining and ore dressing. This fact makes desirable the separate treatment of the statistical data. Generally speaking, the tables reflect closely the conditions of the industry.

## Silver in Peru

It is reported in the *West Coast Leader* that the company operating the Caylloma mine, in Peru, has been re-organized under the name of Sociedad Explotadora de Caylloma Consolidada, with a capital of £100,000 in shares of 5s. each. Reports from the mine are to the effect that on the No. 5 level a vein 20 in. wide and assaying 396 oz. silver per ton has been discovered. The electric driven pumps on the sixth level have given such satisfaction that two more have been ordered. A deep drainage adit 2600 metres long is now being driven to cut the vein on the eighth level. Progress in driving is at the rate of 28 metres per month, and it is expected to increase it to 40 metres per month soon by the use of larger air drills.

NEW CONSTRUCTION at South African mines is rather extensive just at present. Orders will soon be placed for large additions to the concentrating plant of the Messina copper mine and to the plant of the Transvaal Coal Trust, Ltd. A new plant to handle pyritic ore will be built at the Mali Dyke gold mine, in the Pilgrim's Rest district, and additions and alterations will be made to the cyanide plant of the Benoni Consolidated, while at the Mystery mine, in Rhodesia, a complete new plant will be built. A mill of a capacity of 15,000 tons per month will be built at the Cam and Motor mines. The plant of the Sabi mine will be enlarged, as will that of the Cinderella, and the purchase of a small mill for the Rhodesia Gold Mining & Investment Co. is under consideration.

## Book Reviews

Any of the books noticed in this column are for sale by, or can be procured from, the MINING AND SCIENTIFIC PRESS.

**BUSINESS LAW FOR BUSINESS MEN, STATE OF CALIFORNIA.** By A. J. Bledsoe. Business Law Pub. Co., San Francisco, 1912. For sale by *Mining and Scientific Press*. Price \$4.75.

This is the fourth in a series of manuals by the same author and covering the business laws of Oregon, Washington, and New York. The books are designed, not to do away with the lawyer, but to give to the intelligent business man that general knowledge of the law which will enable him to avoid many troubles. It starts with 'Business Contracts and Legal Obligations' covering a wide variety of topics from accident insurance to wholesalers' agents. Following this are chapters devoted to: Collection of Bills and Accounts; Notes and Mortgages; Attachments, Judgments, and Executions; Last Wills; Corporations in California; Bank Laws of California; Mines and Mining; Water and Water Rights; Administration of Estates of Deceased Persons; United States Bankrupt Laws; Automobile Law of California; Taxes and Tax Titles; Trust Deeds; Assignment of Contracts, Guarantee of Accounts, and Powers of Attorney. The book contains a particularly complete table of contents, but no index. It is highly commended by the judges of the California supreme court.

**REINFORCED CONCRETE BUILDINGS.** By Ernest L. Ransome and Alexis Saurbey. McGraw-Hill Book Co., New York. Pp. 235. Index. For sale by the *Mining and Scientific Press*. Price \$2.50.

The large number of competing methods for reinforced concrete construction that have come into vogue during the past few years have resulted in a great deal of confusion in the minds of possible users. Mr. Saurbey presents a history of the development of the use of reinforced concrete since its inception, together with an analysis of the basic patents, which in itself will be of great value to all engineers who desire to possess a thorough understanding of the subject. The rational design of reinforced concrete buildings is extensively discussed, and is treated under the subdivisions of adhesion, compression, and lateral expansion, bending, transverse stresses, applications to the bending theory, initial and allowable stresses. Practical construction is also treated at length, the first subdivision including materials of construction, floor estimates, foundations, finishing operations, fireproofing, and various repairs to existing buildings, accidents, superintendent's specifications, and the theory of beams. The theory and application throughout is comprehensively treated. The book contains many tables and illustrations.

**THE EXAMINATION OF PROSPECTS.** By C. Godfrey Gunther. Pp. 222, ill., index. Pocket size, flexible cover. McGraw-Hill Book Co., New York, 1912. For sale by the *Mining and Scientific Press*. Price \$2.

This book is designed to assist the engineer in the selection of prospects worthy of purchase or development. It does not cover the general subject of mine examinations, though in the first chapter pertinent suggestions as to the essentials of such examinations are made. The main part of the book is concerned with the geology of ore deposits, excluding iron and the non-metallic minerals. Properly enough, the greatest attention is devoted to the structural features of ores, followed by chapters discussing primary and secondary ores and the criteria for their recognition, the forms of ore-shoots, and the characteristics of outcrops. The material has been carefully compiled, well sifted, and is well illustrated. The criticisms of the author are well put and valuable. While the book will not do away with the need for a thorough grounding and continuous study of the literature of ore deposition, it is much the best thing of its kind yet written and should do much to cultivate a sound discrimination in the selection of prospects.

## Decisions Relating to Mining

Specially reported for the MINING AND SCIENTIFIC PRESS.

### TRESPASS ON LESSEE'S RIGHTS—DAMAGES

A lessee, who has the exclusive right to conduct mining operations upon a tract of land for a stated period, cannot recover more than nominal damages from one who has wrongfully removed a part of the mineral, where it appears that the lessee would not, within the life of his lease, have reached the mineral so wrongfully taken.

Chappel v. Foster, (Kansas) 123 Pacific, 870. May 11, 1912.

### PATENT ENTRY CANCELED BECAUSE OF UNEXPLAINED DELAY

An applicant for patent to a mining claim must proceed with diligence to complete his patent proceedings; and where he has not prosecuted his case to entry until more than three years after the completion of the publication of notice, and no satisfactory reason is given for the delay, the entry should be canceled. While a mineral entry allowed on insufficient showing of title in the applicant may be permitted to stand where the applicant subsequently acquires the complete title, he will not be allowed additional time in which to secure outstanding interests or to institute forfeiture proceedings against a non-contributing co-owner, where there has already been an unexplained delay of more than three years between publication of notice of the application of patent and completion of entry.

L. L. Squires *et al.*, (Land Department) 40 Land Decisions, 542. January 25, 1912.

### OIL LANDS—RIGHTS OF CO-TENANTS.

The holder of an undivided interest in oil land can extract oil therefrom without his co-tenants concurring or participating. In case oil was not found he would have to bear the loss of his experiment and cannot call on a non-participating co-tenant for contribution. But if oil is found and marketed, the co-tenant requiring the working tenant to account to him for his interest in the product, measured by his interest in the land, must allow his proportion of the necessary cost of producing and marketing the product. This reasonable expense would include the cost of machinery and appliances and other means necessary to production. In other words, all reasonable expenses incurred in the production and marketing would have to be deducted from the gross value before a division of the proceeds between the co-tenants.

Burnham v. Hardy Oil Co., (Texas) 147 Southwestern. 330. May 8, 1912.

### COAL LEASE—WHAT ARE NOT GROUNDS OF FORFEITURE

A lessor of a coal mine was held not entitled to declare a forfeiture of the lease because of the payment of insufficient royalties, where the lessee had made an error in his calculation of weights, but had paid each instalment in good faith and in belief that it was paid in full, and it was so accepted by the lessor at the time of payment, provided the lessee is solvent and willing to pay the amount of any shortage found by the court. A covenant against sub-leasing, when relied upon as grounds for forfeiture, will be strictly construed by the court, and where possession of the mine was surrendered by the lessee to another company under a working contract, such contract will not be construed as an assignment entitling the lessor to declare the lease forfeited. Nor can a forfeiture be sustained for improper development of the property where the lessee acted in good faith, and the proper manner of development was largely a matter of judgment.

St. Louis Union Trust Co. v. Galloway Coal Co., (Alabama) 193 Federal, 106. December 2, 1911.

## Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

**QUICKSILVER** is consumed mainly in the manufacture of fulminate for explosive caps, of vermilion, of drugs, of electric lighting apparatus, of scientific apparatus, and in metallurgy in the recovery of gold and silver (principally gold) by amalgamation.

**BARITE** is sold ordinarily in the crude state to mills. In the latter it is washed to free it from iron stains, then ground and treated with sulphuric acid. The principal production comes from Missouri and the crude material sells for \$2 to \$4 per ton at the mine. After it has been treated in the mill it sells for \$10 to \$12 per ton. Higher prices are paid for the finest products, such as 'extra ground and floated.' The market is mainly in the East.

**ANTIMONIAL** tailing presents much difficulty in cyanidation and the following are the chief points to be watched. (a) The strength of the working solutions so that the selective action of the gold will be at a maximum while the solution of the sulphide of antimony is at a minimum, also the consumption of cyanide; (b) the amount of protective alkalinity present; this must be such that the consumption of cyanide is kept down; yet it must not be too pronounced, as in that case the solution may dissolve the sulphide of antimony and refuse to take up the gold present; (c) treating the precipitate, which always contains more or less antimony in metallic form; (d) the final production of clean gold.

**MACHINE-DRILL** footage at the Ready Bullion mine of the Alaska United varies but little according to the character of the work. During the year 1911 the average footage drilled in the mine per 8-hr. shift was 34.18. In stoping 32.71 ft. was drilled per shift, 34.91 ft. in cutting out, and 35.57 ft. in development. The tonnage broken varies greatly, however, amounting to 57.7 tons per shift in stoping, 16.94 in cutting out, and 8.64 in development. The tons broken per foot drilled amounted to 1.764 in stoping, 0.485 in cutting out, and 0.242 tons in development. The average, found by dividing the total footage for the year by the total tonnage, was 0.95 ton per foot drilled. The average cost per shift was \$8.59 for labor, \$2.88 for explosives, and \$5.38 for supplies, power, etc.; a total of \$16.85. The average cost per foot drilled was 49.2c., or 51.8c. per ton broken.

**WORK** existing upon claims when located cannot be entered, except by fraud; for the applicant must make oath that work entered was performed by himself or grantors. Where the claimant re-locates his claim to prevent others from locating it through his failure to do the annual labor, it is believed, though there is no decision or ruling on that point, that he has lost all prior work for patent purpose. It may be said in favor of the claimant, when making his patent application, that he has actually performed the work he reports, and if there has been no intervening location, and his re-location being more a nominal location, his rights date back to the first location on the principle of resuming work. Against him is the \$500 expenditure implying that the work must be done on the location entered for patent, and not under a former location; also, that he should be penalized for trying to avoid annual labor by losing for patent purposes the work which he re-located. If the forfeiting owner has the right to re-locate his own ground just as a stranger would have, as the court held in one case reported, then he should have no patent rights to his old work, just as a stranger would not. At any rate, the claimant should resume work on his forfeitable location instead of re-locating; he should make amended locations instead of re-locations, whenever defects or changes of location are to be adjusted.

SULPHUR, PYRITE, AND SULPHURIC ACID IN 1911. By W. C. Phalen. With Notes on the Manufacture of Sulphuric Acid from Smelter Fume at Ducktown, Tennessee. By F. B. Laney. Advance chapter from 'Mineral Resources of the U. S., 1911.' U. S. Geol. Surv. 30 pp.; tables. Washington, 1912.

## Commercial Paragraphs

The Ophir Consolidated Mining Co., Ophir, Utah, will make additions to its electrical equipment consisting of one 50, three 35, and one 15-hp. motors and three 50-kw. transformers. This apparatus will be supplied by the GENERAL ELECTRIC Co. The Homestake Mining Co., Lead, South Dakota, will add five motors to the electrical equipment in its mines. These consist of one 10, two 15, and two 25-hp. motors, and will also be furnished by the GENERAL ELECTRIC COMPANY.

THE TRAYLOR ENGINEERING Co., Allentown, Pa., reports that business is good, and that some of the orders recently received are as follows: Three sets of 'AA' extra heavy 42 by 16-in. crushing rolls for the Miami Copper Co., two sets of 36 by 16-in., and one set of 30 by 16-in. heavy-duty rolls for the Ophir Hill Con. M. Co., a re-grinding plant for the United States mint, New York City, consisting of crusher, 6-ft. Chilean mill, driers, etc.; 18 water jackets constructed of American ingot iron for the Garfield Smelting Co.; one heavy-duty jaw-crusher for the Nelson Contracting Co.; 32 water jackets for the Mason Valley mines Co.; a complete set of furnace jackets for the U. S. Smelting Co. constructed of American ingot iron; a set of 18 by 10-in. heavy-duty rolls for the Ridgeview Sand Co.; a special fine jaw crusher for the Bedford Feldspar Co.; a set of water jackets for the Ducktown Copper Co.; 35 water jackets for Phelps, Dodge & Co.; a complete 200-ton amalgamating, concentrating, and crushing plant for the McIntyre Porcupine Mines Co.; a No. 7 1/2-in. gyratory crusher for the U. S. Gypsum Co.; and many small orders.

The O'Kelly safety hook manufactured by J. G. O'KELLY Co., Chicago, differs from others in that the load is carried from two points instead of one. The link or clevis not only keeps the load from slipping off, and the hook from straightening out, but supports one-half the load in conjunction with one leg of the hook. The other half of the load is carried by the flat-sided pin through the other leg of the hook. A slot in the upper end of the hook part of the device, with an enlarged or full circular portion at the bottom, admits the hook being raised, and then swung about the flat-sided pin as a centre. It will swing only when the pin is in the enlarged portion of the slot, consequently, after it is opened, the hook must swing into position before it will drop and engage with its two points of support. All forces act in direct lines and there is no possibility of the hook binding. The centre of the load is in line with the centre line of the hook, therefore the hook must close and lock the instant any load is applied. Conversely, the hook cannot be opened until the load is released.

The great importance of non-return boiler stop valves for use on a battery of boilers is universally acknowledged, and in some countries their installation is compulsory. It is evident that should a tube be blown out or a fitting be ruptured in one of the boilers of a battery, the steam from the other boilers would rush into the header and discharge into the disabled one. An ordinary stop valve would here be inadequate, as considerable time would necessarily be consumed in reaching and closing the valve, and a certain amount of danger must be anticipated. The non-return safety boiler stop valve manufactured by THE LUNKENHEIMER Co., Cincinnati, Ohio, has been given very severe tests, and is in use in a large number of high-pressure power plants, in all cases giving perfect satisfaction. When these valves are used, should an accident occur, such as the blowing out of a tube in the boiler or any rupture of the headers, shells, etc., permitting the steam to escape, the valve will immediately close. The plant can be operated with the other boiler or boilers, without interference, thereby preventing the closing of same and the loss of time and money. This valve will prevent steam from being turned into a boiler which has been cut out for cleaning or repairs, as it cannot be opened by hand when pressure is on the header side. It can, however, be closed when desired. The valve can be connected either horizontally or vertically.

## EDITORIAL

FOREIGNERS are returning to Mexico and south-bound trains and steamers are now well loaded. This is an excellent sign, as the men going back are those who know Mexico well.

WESTERN metal mining is to receive serious consideration at the hands of the United States Bureau of Mines if the recommendations of the Senate committee stand. Amendments to the Sundry Civil bill made in the committee provide the \$100,000 recommended by the secretary for investigation of technical problems relating to metal mining, and also make ample provision for mine inspection in Alaska. It is to be hoped that the conference committee will allow these items to stand.

PROTEST against change is to be expected, and the metallurgists who have been introducing stage crushing, filter-pressing, and other new features in Rand practice have criticism to meet as well as praise. We republish this week an article by Mr. H. Stadler, printed first in the *Rand Daily Mail*, in which exception is taken to the principles advocated and claims for results on behalf of the metallurgists of the new school. We print this because it is interesting and the best statement we have seen of the position of those who cling to the old practice, and because the author feels that he has not had a fair opportunity to present his case before his local audience. Without entering into the merits of this contention, we are glad to give the material to our readers. To metallurgists away from the Rand the essential question is whether or not the newly introduced methods do actually yield better results. At the proper time we shall hope to have something to say as to this.

CONVERTERS for the treatment of copper matte were first made of a shape similar to the bessemer converter, and the persistence of association of ideas of the two operations is so strong that reference is still made to the 'bessemerizing' of matte, though the action in the copper converter bears little resemblance to the converting of steel, beyond the fact that both are produced by blowing air through a molten mass. In the early converters the tuyeres were placed some distance above the bottom, with the idea of keeping them above the level of the copper formed in the operation. At the Copper Queen this plan was varied by making the longer axis of the converter horizontal, placing the tuyeres in a row on the near side, and by tilting the converter the incoming air was kept above the copper. Both types proved successful, and a semi-geographical distribution of form developed; the plants in the Southwest using the horizontal or Bisbee type, while in the Northwest the vertical or Anaconda form was preferred. Changes in practice have eliminated some of the early considerations, and the present-day converter foreman finds it difficult to believe that the preventing of the blowing charge from getting too cold was ever a problem. At Great Falls the upright type has evolved into a converter 12 feet in diameter and about 15 feet high, using

air at 12 pounds pressure, as compared with the 5½ pounds of the early Bisbee form. The deeper column of matte and higher blast pressure is more effective to produce rapid oxidation, the circular cross-section gives much more effective support to the lining, and is more convenient to reline. Mr. E. D. Peters some time since prophesied an eventual return to the upright form of converter, and the recently announced intention to adopt the Anaconda form for new construction at Cananea, where the Bisbee type has been in use, is strong evidence of fulfillment of the prophecy.

### California Miners Association

The California Miners Association is to be resuscitated. For many years this organization spoke authoritatively for the miners and mining industry of California and wielded a powerful influence. Through a series of county locals, it kept in touch with every part of the state and, with thoughtfully planned and carefully executed campaigns, it brought to bear upon the State Legislature and upon Congress the force of informed public opinion in mining matters. The Association was organized primarily to help the hydraulic miners in their contest with the farmers. Its most important single achievement was the securing of the passage of the Caminetti bill through which it was hoped that the revival of hydraulicking would be made possible. That no such result followed does not detract from the credit due the Association in framing and securing the law. Its failure was in resting too easily upon well won laurels and allowing an effective fighting force to disintegrate until only a corporal's guard remained. The Association, however, made clear the fact that the mining industry can be organized on a democratic basis, and that when that is accomplished the opinion of the miners will command respect both at home and abroad. Mining men, if they will but settle their differences among themselves, can have anything in reason that they are minded to ask of Congress or the legislature of any Western state. They must, however, take into account the whole industry, and their opinion, when expressed, must be honest and reasonable. Facts are the most potent of arguments and an organization that can marshal facts will accomplish much.

To achieve results of moment any such movement must be non-partisan and non-political. Whether a Democrat or a Republican be in the presidential chair is of less importance to most mining men than is the question of what constitutes the discovery necessary to legal location of a claim. Just what form conservation legislation is to take, may well mean more to a California oil man than the exact amount of the tariff on wool. Mining men should get together and make their influence felt, but they should recognize that to do so requires a spirit of conciliation within, as well as without their ranks. The fact that the old California Miners Association did actually accomplish results, affords the best omen for the new movement.

The immediate occasion for again calling the Association together is the need for preparing for the Panama-Pacific Exposition. It is elemental that an exposition in San Francisco must excel in mines and mining, whatever may happen to other departments. It was the gold and silver of the Incas that first created a traffic across the Isthmus. It was gold that brought people to California and established industry on the Pacific Coast. California was known first and is known best as the Golden State, and if ever mining, and especially gold mining, is to be prominent in an exposition, it must be in 1915. It happens that gold mining is a non-competitive industry. The owner of a gold mine has nothing personal to gain by advertising his wares. What

he gives to an exposition in the line of time, money, or material, he must give for the benefit of all, to promote general education, and with the hope of indirect gain only. It is therefore vital that the fullest coöperation of the mining men be secured if a successful exhibit is to be prepared, and anything less would be a reflection on the great primal industry of the West. In all this California does not stand alone. Nevada, Arizona, Utah, all the Western States, need development. They need more mines and they will benefit from stimulation of the mining industry. In each, as in California, there is little personal and direct interest in preparing an exhibit. Having all this in view, it is proposed to call a meeting of the Association sometime in November and to invite to it delegates from outside as well as inside the state. The first business will be to effect that coöperation with officials of the Panama-Pacific Exposition that will assure making the mining exhibit at San Francisco in 1915, not the largest, but the best exposition of mining ever brought together. That being accomplished, it is probable that the convention will turn its attention to other problems since many of the more acute are sure to come up for consideration. A call for the meeting is being formulated and will be issued in a few weeks. The matter is in the hands of a committee consisting of Messrs. Charles G. Yale, E. B. Braden, and W. C. Ralston, and the project is sure to be pushed vigorously and effectively.

### Copper Prices and Surplus

Copper led the market in New York last week so far as public interest was concerned. The followers of the metal market in America have no way of speculating in the metal. In London speculators can traffic in copper warrants in much the same way as traders in this country can deal in grain and cotton. This fact makes London the speculative centre for metals, and when the sensational break occurred in the copper metal market last week, it made its appearance first in London. On Tuesday there was a drop of some £3 per ton, and later in the week quotations on this side went down from 17¾, to 16½ bid, 17 asked. The copper share list reflects the attitude of the public in that it has been much more sensitive on the decline than it has been on the advance in the metal. It was a foregone conclusion that any break in the market would be accompanied by rumors concerning hidden stocks of copper. This story has been put out in so many different forms and in each so strenuously denied, that in order to make the denial good the real explanation had to be brought to the surface. It is true that there has been no mention made in the general press of the requirements of the European governments for war purposes, but there are now appearing tacit admissions of the piling up of blister copper at the refineries in unknown quantities. In a way it may be accepted without argument that this does not constitute a hidden stock of copper, but it does constitute a factor unknown so far as the consumer and the general public is concerned, and it does give to those who are in position to obtain inventories from the smelters a very great advantage. The consumers, especially on this side of the water, have for the past two or three years counted upon the production from the 'porphyries' as a very important element and one that would hold the price of copper within reasonable bounds. It is true that blister copper cannot be counted as a part of the world's visible supply, but the consumer will certainly remain unwilling to fill up his stock-yard at 16 cents or better, so long as there is a possibility of the refiners rushing an accumulation of blister copper into the market immediately after and disposing of it across the water at 13 cents or even lower, as was done two years ago.

Much is being made of the labor conditions at Perth Amboy, but these conditions are hardly sufficient to account for the discrepancy between mine and refinery output. In reality the copper metal situation is in the hands of a small circle of producers, smelter men, and refiners, and it is true that there is nothing to compel the producers to market their product any faster than they see fit, or to manufacture the raw material except as they deem to their own best interest; but the present move is the result of a huge manipulation which has not been carried to a successful completion. In some quarters the attempt is made to estimate the amount of blister copper withheld at the refineries, and 100,000,000 pounds has been published as the total. In fact it would be almost impossible to compute this correctly except by actual inventory at the various plants. It would not be very difficult to arrive at a conclusion by comparing refinery output with mine output if it were possible to secure a definite starting point. Inventories carry no meaning except as compared with previous inventories and in this case no previous inventory exists. If the tape tells the story, and that it does is one of the principal tenets of faith in Wall Street, the copper situation is not so rosy as most of the selling agents endeavor to make it appear. It is a significant fact that a great many of the leading copper shares are selling lower now than they did two years ago when the metal was selling for 12½ cents per pound.

The July figures of the Copper Producers Association showed a decrease of 5,280,638 pounds in accumulated stocks, the copper surplus being 44,335,000 pounds, something less than 14 days output at the present rate of production. While absolutely no suspicion attaches to the figures given out by the Association, it is plain that market followers do not consider these figures as covering the real position of the metal. A great deal is said about the increased foreign demand for copper. As a matter of fact, the increase in exports has been almost entirely due to the needs of Germany, and the German situation is very far from satisfactory. Industrially the country is very much over-extended, and that Berlin finances are in a delicate condition is widely whispered among international bankers. The real salvation for copper lies in the resumption of constructive activity at home—the building of much needed hydro-electric power plants, the electrification of railroad systems—and it is plain to everyone that the political situation and the business situation in this country are so interlocked that at present business interests are all playing politics.

### Financing the Institute

Over a year ago the council of the American Institute of Mining Engineers proposed certain radical changes in the constitution and by-laws. Among these was a plan to increase dues of members. At the general meeting last February action on these amendments was deferred and a committee consisting of Messrs J. F. Kemp, C. R. Corning, George C. Stone, W. H. Nichols, Jr., and A. R. Ledoux, was appointed to investigate the affairs of the Institute and report whether an increase was necessary in order to maintain the standard of work already set and to make due provision for the future. The committee was charged with other duties, but for the present we are concerned only with the financial problem. The committee finds, in brief, that the Institute is living beyond its income and has been doing so for several years. The principal reason for this is the debt incurred when the Institute moved into its new quarters. It will be recalled that with practical unanimity the members voted to accept a share of Mr. Andrew Carnegie's gift of a building in New York, and assumed re-

sponsibility for payment of \$180,000 of the money necessary to purchase the ground. Of this amount \$105,700 has been paid and \$6000 subscribed; the money having been given by only 90 of the 4000 or more members. It is worth noting also that members living in the West have made no contribution to this fund. In the main we, speaking for the membership at large, have accepted the large gifts of the few, and have made no contribution of our own. In order to pay the remaining portion of the debt and interest by January 21, 1925, which allows one year for contingencies, 12 annual payments of \$7884.81 will be necessary. Having in view the fact that the annual income of the Institute is now from \$50,000 to \$60,000, this does not seem a large amount to set aside for such a series of years. In fact, however, the committee finds that the Institute is not only not providing for these payments, but is running behind \$2000 per year on current expenses, and has already used \$18,708.76 of the accumulated funds on hand when the change of headquarters was made. The remaining surplus January 1 was \$4231.

The income for the year 1912 is estimated at \$53,537. The principal items are: dues, \$35,500; net advertising receipts, \$5000; sale of publications, \$4000. The remainder are made up of extra charge for binding, life memberships, initiation fees, interest, and minor items. It will be noted that the expected income from dues is much less than the total found by multiplying the number of members by the rate for dues. The reason is that a considerable number have purchased life memberships and others are perennially delinquent. As no separate fund has been kept to cover the receipts from life members, all such, and the delinquents, involve an annual expense on the part of the Institute. This is estimated by the committee at \$3.50 per person. The expenditures for the year, including the annual payment for the land, are estimated at \$64,741. The principal items are: printing and binding, \$19,557; salaries and clerical assistance, \$18,054; meetings and stenographer, \$1000; freight and expressage, \$4500; miscellaneous office expenses, \$1515; library, \$3850; building expense, \$4500; interest, \$2960; annual payment on land, \$7500. Taking into account the surplus, this leaves a net estimated deficit January 1, 1913, of \$11,204. Faced with these figures the committee had no alternative and made recommendations to the council and directors for economies which it is hoped will bring the expenditures down to the amount available for this year, whatever the Institute may decide to do as to the future.

It is not to be taken from what has been said above, and the committee is careful to point this out, that the Institute as a business institution is insolvent. It has, in fact, property worth a half million dollars or more and an income which can be made to cover its necessary expenses. The United Engineering Building is a good investment. It not only affords admirable headquarters for the societies, but it dignifies the profession in the principal American city. When the land debt is cleared, the annual charge to the Institute will not be more than would need to be paid as rent for suitable quarters. It was expected that the land would be paid for by general subscription, and more than half the money has been so raised. Whatever may be the means adopted to secure the remainder, the total necessary, some \$2 per member for a dozen years, is not large. In the meantime the Institute, as well as its members, faces the problem of increased cost of living. Some additional expense is inevitable from year to year. Other expenses, while extremely desirable, are optional, and where to draw the line is the problem for the Council and Directors. In making a wise decision the painstaking and candid report of the Committee of Five will be of the greatest assistance.

# Silver Mining at Cobalt, Ontario

By REGINALD E. HORE

Cobalt mining companies in 1911 had a very successful year, and the district made new high records for both silver produced and profits earned. The output was 31,507,791 oz. worth about \$16,000,000. The profit made was over

In spite of the large production during 1911, there is probably as much ore developed as a year ago, and a large production for 1912 is assured. A number of rich ore-shoots were discovered during the year, and improved meth-

\$9,000,000. Dividend paying companies distributed \$8,620,558, and two privately-owned mines made large profits. At the end of 1911 the silver mining companies had paid in dividends a total of \$30,391,095. The output for producing years 1904-1911 was 125,571,980 oz., valued at about \$65,000,000, and yielding to the mine-owners a profit of about \$35,000,000. A noteworthy feature of 1911 shipments was the falling off in the total tonnage, and increase in amount of concentrates and bullion. It is to be expected that the tonnage shipped will continue to decrease, while the proportion of concentrates and bullion will become greater. An important advance in metallurgical treatment is a process of amalgamation and cyanidation being used at the Nipissing mine for winning the silver from high-grade ore. It is stated that in modified form this process can be successfully applied to the treatment of low-grade ore, and a mill is now being constructed for the purpose. In 1910 there were 14 mills in operation at Cobalt, and two additional ones were built in 1911. The Nova Scotia mill was to treat ore brought by aerial tram from the Crown Reserve, Kerr Lake, and Drummond mines, but has been recently closed down.

ods of treating low-grade ore make it possible to now include as reserves a large tonnage which was formerly of doubtful value. It must be kept in mind, of course, that each year's work leaves a very much smaller area to be prospected; but there is still a considerable area in which

Various other mines	31,275	300.0	317,471	1,058	104 " 1
Totals	305,569	7,014.3	7,084,740	Av., 1,030	Av., 43.5 to 1

it is reasonable to expect that some rich veins will be found. Aside from the rich ore there is certain to be mined a very large tonnage of low grade.

The accompanying table, No. I, from the report of T. W. Gibson, deputy minister of mines, gives the results obtained in the years 1904-1910, and brings out the rapid increase in production of concentrates in the past few years. The ore milled averaged about 30 oz. per ton. Table II, also from Mr. Gibson's report, shows the results obtained by concentration in 1910.

found, but there are apparently but few large faults. The nature of the smaller faults is indicated in Mr. Robbins' section of the McKinley-Darragh mine, Fig. 2. An interesting feature of recent explorations is the work being done along what is known as the 'big' or Cobalt Lake fault. This, the only great fault which has been disclosed in the mine workings, is a thrust dipping to the east at an angle of 62°. On either side there are minor thrust-faults dipping at low angles, and frequently displacing the veins for a few feet. The actual vertical displacement along the big

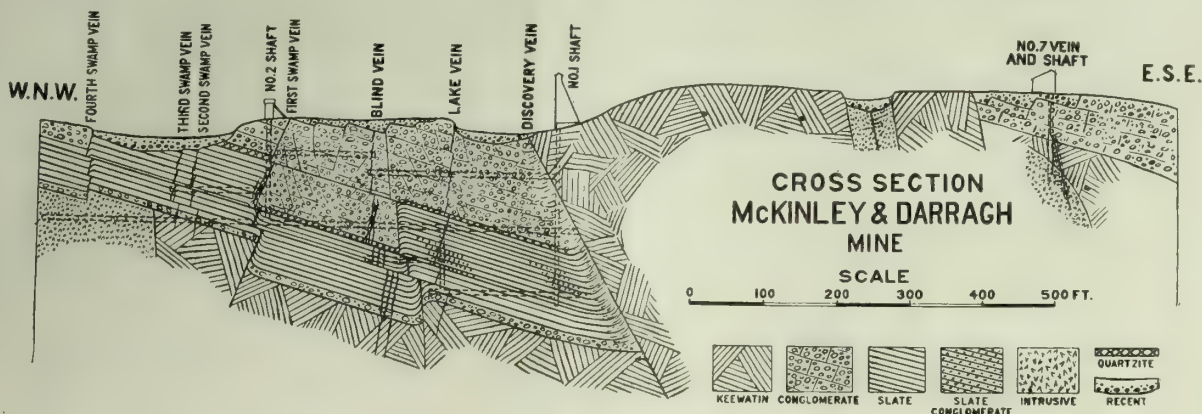

FIG. 2.

During the year preparations have been made for exploring at somewhat greater depth. There has been a remarkable disinclination so far to test some ground that seems not unlikely to contain ore at lower levels than the present workings. This delay is chiefly due no doubt to the fact that where the ore outcrops at the surface, the ore-shoots have generally failed at a depth of less than 200 ft. In most cases the decrease in value occurred near the bottom of the

fault is not known, but, as may be seen from Mr. Robbins' cross-section, Fig. 2, it is at least 300, probably 400, ft., and possibly much greater. From the cross-section it will be seen that at the McKinley-Darragh mine the ore-bodies are on the down-throw side, in Huronian sediments, and that there are no corresponding sediments remaining on the up-throw side. They have evidently been eroded. At the north end of the lake, however, what is probably the

BATTERY, NORTHERN CUSTOMS MILL.

HYDRAULIC PROSPECTING.

Huronian formation, and the underlying Keewatin has produced comparatively little. Since in nearly every case where the ore outcrops at surface, the Huronian is there comparatively thin, the mines so far are all shallow. In some cases rich ore is found in the underlying Keewatin, but the shoots are usually less regular.

The accompanying illustration, Fig. 1, showing the workings at the Coniagas mine, indicates the form of the ore-shoots in the case of deposits in Huronian sediments lying unconformably on the Keewatin complex. It has been found that the ore pitches down in a direction parallel to the contact. It outcrops in places where the conglomerate is thin and the shafts and most of the workings up to date are thus situated. The result of development indicates that deeper ore will be found farther from the outcrop. The deposits are being developed by a step-like series of drifts and winzes. The valuable deposits being chiefly in the Huronian, it is not likely that the ore-shoots will continue to great depths; but it is quite probable that some ore will be found a few hundred feet deeper than most of the present workings.

<sup>1</sup> In most of the mines numerous small faults have been

same fault, shows Huronian sediments at the surface, on both up-throw and down-throw side. The ore deposits which have been worked here are on the up-throw side, and it is not unreasonable to expect that similar deposits occur at greater depth on the down-throw or western side.

At the La Rose mine a winze is now being sunk to investigate the possibilities at greater depth. The main shaft at the La Rose, after passing through about 150 ft. of Huronian conglomerate and quartzite and about 50 ft. of Keewatin schists, cuts into Huronian conglomerate again. This second conglomerate, while undoubtedly Huronian, differs from that at the surface. It is characterized by numerous pebbles of gray chert. The conditions at the La Rose mine are illustrated by Fig. 3, which is based on a section described by W. G. Miller and C. W. Knight,\* of the Ontario Bureau of Mines, and my own notes. Mr. Knight states that the vertical displacement at the La Rose mine is 233 feet. Messrs. Miller and Knight† also studied the fault in the workings at Cobalt Lake, and found the structure to be similar to that at the McKinley-Darragh and La Rose

\*Bulletin Canadian Mining Institute, Feb. 1912, pp. 21-26.  
†Eng. & Min. Jour., Sept. 30, 1911.

mines. According to A. A. Cole, the fault was also found in the early workings at the Right of Way mine. Where first found there are Huronian sediments on both up-throw and down-throw side; but one is a coarse conglomerate and the other a greywacke with but few pebbles. Of deposits in the Keewatin series the most extensively worked are

FIG. 3.

those at the Temiskaming mine. The accompanying maps, Fig. 4, showing stoping on No. 1 and No. 3 veins up to December 31, 1911, illustrate the mode of occurrence of ore-shoots. The Keewatin series in which the deposits occur has been penetrated in some of the workings and the underlying diabase has not yet proved productive here.

FIG. 4.

The veins at Cobalt are nearly vertical, only a few inches wide, and usually in hard firm rock. In mining the ore in the early days it was the practice to break only enough of the wall-rock to make it possible to take out the vein matter. The drifts and stopes were often made so as to leave the vein standing on one wall. The broken rock

was cleared out and then the ore taken down by the aid of hand-picks. In this way a clean separation of vein matter from wall-rock was made in the mine. It was soon found that there are often several narrow veins running nearly parallel, and spaced only a few feet or a few inches apart. It then became necessary to break vein and rock at the same time. The high-grade ore then became intimately mixed with wall-rock, and it was necessary to pay more attention to sorting methods. The sorting was then done at the surface, on various types of tables and belts. The rich ore was picked out and the discard went on the dumps.

The material on these dumps was found to contain quantities of recoverable silver, and in 1908, the treatment of low-grade ore was first extensively undertaken. In most cases it was found that rock taken from a few feet in either side of a rich vein contains enough silver to make milling profitable. This silver is not commonly disseminated through the rock; but occurs in the narrow crevices.

The successful operation of the first mills led to the building of several others, and when these were running, the companies that had taken out high-grade ore broke large tonnages of low-grade from the old stopes. In mining new ground the companies owning mills revised their method so as to break both high-grade and low-grade ore at once, and improved the methods of ore-sorting so that the finely broken particles of rich ore would not be left with the low grade.

At the Nipissing mine the present practice in mining is to sink a vertical shaft on the lode and to develop ore at levels less than 100 ft. apart. Drifts are run following the vein, which is kept well within the face. The drifts are cut wide and high. On the Meyer vein the drifts are 12 ft. wide and 14 ft. high; a 5½-ft. cut being taken off with but one set-up. On most veins the drifts are 5½ to 6 ft. wide and 14 ft. high. In development work 2-man piston drills, and in stoping 1-man hammer drills, are used. In stoping, a filling system has been found satisfactory. The level is

protected by a lagging of poles laid on caps supported by posts. At intervals of about 25 ft. chutes are built in for drawing off the ore. The ore is then broken down onto the timber, and enough is drawn off to leave the desired space for miners. The rock on both sides of the vein is broken, and there is no sorting whatever done in the stope. The ore

lies as it falls, and becomes intricately mixed before it reaches the surface. The conglomerate in which so great a part of the rich ore occurs, has a tendency to break into large pieces. These are 'bulldozed' in the stope so as not to choke the 4-ft. chutes.

From the chutes the ore is run into small cars. These are trammed to the shaft, hoisted in the cage, and trammed to ore pocket or mill stockpile, according to the tag placed on them in the mine. From the pocket the ore is fed automatically to a table. It first, however, passes over a plate perforated with  $1\frac{1}{2}$ -in. holes. The undersize goes to a trommel. From the trommel the fine goes to a Wilfley table and oversize to jigs. These jigs are of a type constructed especially for the ore by H. E. Kee, of the Nipissing mine, and are apparently very successful. All the ore which passes over the  $1\frac{1}{2}$ -in. holes is washed by a sprinkler. The washings go through a screen to the Wilfley table. The ore passes to the table, where it is hand-picked by four or six men. The sorters pick out two grades—high and low grade—and the remainder goes into a chute, from which it is loaded into a car and taken to the mill-rock stockpile. Sand from the Wilfley tables passes into a simple dewaterer and slime is allowed to settle in tanks, the water being re-used.

## Cyanidation of Pyritic Ore

By F. B. REECE

The cyanidation of concentrates and of ores of high sulphide content, has been described, and the difficulties attendant discussed, by J. W. Hutchinson, A. B. Parsons, Huntington Adams, and others.

Some heavy sulphide ores which do not offer any special difficulties as regards excessive consumption of chemicals, and which yield a satisfactory extraction to cyanidation, give much trouble from a mechanical point of view. I was called upon to operate a plant, situated in a remote district, which had been designed and erected by others to treat an ore of this character, a mixture of arsenopyrite, pyrite, galena, and blende. The equipment consisted of stamps, tube-mills, cone-classifiers and thickeners, 'Brown' type agitators, and vacuum leaf-filters. Supplies and renewals took from four to six months from date of order to reach the mine. The valuable part of the ore was the sulphide, and to maintain the ore at a profitable grade it was necessary to sort it so that it contained from 20 to 25% of sulphides. Due to the necessity of using very soft local pebbles the re-grinding was not as fine as is desirable for the proper agitation of such material. On an average 90% passed 200 mesh.

The supply of air for the four  $27\frac{1}{2}$  by 10-ft. tanks was inadequate. Allowing for the altitude, 7000 ft., it amounted to a total of 32 cu. ft. of free air per minute at 25 lb. maximum pressure. It was found impossible to do more than agitate two tanks at one time, and continuous agitation was out of the question until additional capacity in air could be provided. The design of the central agitation pipe was faulty. It was originally 16 inches in diameter and was far too large, and set so low that there was only a 3-in. annular space between the bottom of the pipe and sides of the cone of tank. This space would probably be too small to prevent choking while agitating a purely silicious slime, it was found to be quite inadequate for the material under discussion. After long and expensive delays and when two or three charges had been lost, the centre pipes were replaced by others of 11 in. diameter placed so that their lower ends were 22 in. from the apex of cone, giving a clearance of about 7 in. between pipe and side of cone.

Bernard MacDonald has drawn attention to the necessity of using the smallest air-lift tube consistent with the amount of liquid to be pumped. His opinions were certainly justified in this case. Smaller pipes than 11 in. would probably have been advantageous, but none were available.

Further, the suggestion put forward by Lloyd Kniffin of reducing the length of the central pipe, was carried out,

leaving the pipe about two-thirds of its original length. These alterations caused a great improvement in the agitation. To assist in keeping the solid matter in agitation during the time of filling and emptying, two holes were cut in the lower part of centre pipe on opposite sides of pipe. The tendency to settle was much reduced by this simple expedient, and it was decided to cut two more holes about 8 or 9 ft. higher up, but unfortunately no opportunity was afforded for trying this experiment. The effect of these apertures on the circulation of pulp was very noticeable as the level of pulp gradually rose during filling of a tank. It is questionable if they are an advantage after the tank is in full agitation, but this could easily be overcome in the manner suggested by Mr. Adams at the Natividad mill, where sliding doors were fitted on the central air-lift tube and opened and closed as the level of pulp in tank varied.

Much trouble was experienced from the choking of the  $\frac{3}{4}$ -in. air-agitation pipes which had not been provided with non-return valves. These pipes were the only means that had been provided for agitation, the usual side and 'spider' pipes not having been supplied. It was impossible to install these during the time of running covered by this article. The only remedy was to remove, clean, and replace this pipe after every stoppage of the air supply. To force this down again into the mass of settled slime the end of pipe was closed and drawn out to a sharp point. Two sets of  $\frac{1}{8}$ -in.

IMPROVED AGITATION PIPE.

holes were then drilled through the pipe, the lower set coming very close to the bottom of cone when the point of pipe rested on the apex, and the other set coming 3 in. above the intake of the central column.

Discharging the tanks to pulp-stock tank by gravity was a tedious process on account of the lack of means of efficiently agitating the charge to the last moment. The leaf-vacuum-filter employed gave poor results, as might have been expected in treating material of this weight. It was impossible to prevent segregation and dropping of the bottom and heavier portion of cake. The only kind of filter to use in a case like this is a pressure-filter, making cake very rapidly, and preferably one which has no excess slime to displace. The solution of the difficulty in a case like the foregoing would appear to be the employment of mechanically driven classifiers and thickeners, of continuous agitation, pressure-filters, and a plentiful supply of air to the agitation and pulp-stock tanks. I am convinced from personal experience at the Hacienda Guadalupe, Pachuca, that it is not necessary to use the 'diagonal' method of connecting the tanks in series recommended by Mr. Grothe and Mr. Kuryla. The overflow method used by Mr. Adams gives excellent results, with more simple construction.

The foregoing experience shows how necessary it is to carefully design agitation plants to deal with material containing more than say 6 or 8% of sulphides.

W. P. Lass\* has described and illustrated a valuable device in the shape of an adjustable spider pipe, which can be lowered on top of a settled charge, to gradually bring it into a state of agitation. In agitating this heavy material, it is a great advantage to be able to remove the air pipes at will, as, despite all care that can be taken, choke-ups are not infrequent. Furthermore, a pipe which is in its correct position when the tank is in brisk agitation, may be quite unable to make headway against the depth of settled pulp which overlies it, when a tank has settled for more than a few minutes. It will be noticed in referring to the article by Mr. Lass that the central air-lift pipes are 10 inches in diameter for a 10-ft. diameter tank. Probably a still smaller pipe would be even more effective.

\*Mining and Scientific Press, Oct. 21, 1911.

A. Quartano, of El Oro, Mexico, again falls into the old blunder, already refuted, that the exposure of surface represents the 'metallurgical value' of crushing work done. There is not the least objection to adopting this standard, provided all other factors are reduced to this same unit, especially the assay value, which is taken by weight (or volume), and varies therefore at a much slower rate than the surface exposed. From the statement made by E. H. Johnson<sup>4</sup> that the stamp and tube-mill combination produces, for the given cases, 9.5% more surface than single stamps, the impression is produced, perhaps unintentionally, that the 'useful work' is increased in this same proportion. It follows, however, from data in Table II, that, on the assumption of average values for the various grades the higher extraction obtained in favor of the fine pulp is only 1.5%, or 5.4d. in a 7.5 dwt. ore. This amount is hardly sufficient to repay the higher costs of finer grinding.

2. One of the most important results of the research work done by the Mines Trials Committee is, not the discovery, but the realization, of the fact that any classifier

4. The profit resulting from higher extraction by finer grinding is practically nullified by forfeiting the good effect which a higher percentage of extraction by amalgamation has on the total extraction. Crushing by impact in a mortar box is much more adapted to free the pyrite and gold from the gangue, than the abrasive action of the tumbling contents of tube-mills, in which the particles are not broken up, but largely ground down by surface wear. The greater amenability to amalgamation of battery pulps is borne out by the fact that in Messrs. Denny's time, as well as now, an amalgam extraction of up to 70% was easily reached, while, where the mill plates have been discarded, this extraction has now dropped in most cases to 50% (South Randfontein Mines, 48.6%; East Rand, 50.11%). Besides the advantage of quick realization of profits, a high extraction by amalgamation has a far-reaching effect on total extraction, consequent on the lowering of gold contents left on the final pulp for cyanide treatment, where only 85 to 90% is recoverable under the best actual conditions. Assuming for argument's sake that it were possible to obtain an

with its overflow velocity well adjusted, acts as an efficient concentrator, in which the specifically heavier pyrite particles tend to be retained in the underflow. Roughly, it may be said that the assay values of the + 60 and + 90 grades in the overflow are halved, with a corresponding enrichment of the underflow. For instance, 10% of + 60 grade of such an overflow, assaying 2.5 dwt., yields just as good an extraction as a 5% overflow, assaying 5 dwt. Those experienced in panning know how easily the segregation of pyrite from quartz can be disturbed and upset by hasty and maladroit movements, and it is therefore not surprising that partly banked up and disturbed classifiers are complete failures as concentrators. The abandonment of the old proved spitzkasten in series, in favor of cones in sets, with or without the much-advertised diaphragm, is also an improvement of a retrograde kind.

3. With the very fine final pulps now generally in use, it is no longer reasonable to take the percentages left on the + 60 grade as a criterion for the fineness of pulps. Besides the inaccuracy of screen measurements (which may amount to 2% and over), it must be remembered that some of the particles left on the + 60 grade are of an exceptional flat or long shape, and more amenable to chemical treatment than a similar volume of spherical form; or they are specifically lighter materials, and of a nature quite different from the ore, since they carry neither pyrite nor gold.

amalgam extraction of 90% from a low-grade ore, say 5 dwt., the low residue value (0.5 dwt.) would make the cyanide treatment altogether unnecessary. The argument which has been advanced that the free gold, not extracted by amalgam, is caught in the cyanide works, though borne out by assays of residues, is not conclusive. The maintenance of the accepted standard for residues, even with an enriched final pulp, is simply a matter of more or less thorough treatment and therefore of cost. The actual facts are, that neither the East Rand nor the Crown Mines, with all their up-to-date and costly methods of treatment, have succeeded in raising the percentage of extraction by cyaniding much above the level of 85%, which is easily obtained all over the Rand. The extraction of the East Rand in 1910 was 85.7%, and on the Crown Mines 88.3 per cent.

5. Metallurgical experts coming here from abroad should at once realize that, so far as these fields are concerned, grinding finer than the + 200 mesh is mere waste of energy and money. The reduction of the last few percentages of the + 60 grade by tube-milling cannot be done without the stern necessity of simultaneously grinding down the rest of the pulp. The greater amount of over-worked slime unnecessarily produced inevitably demands more perfect washing and dewatering equipment in the cyanide works, with consequent additional working costs and additional capital expenditure for the machinery required to perform this unnecessary work.

## WORKING COSTS

Accounts and elaborate statistics, although admirably kept at all mines from a purely mathematical standpoint, fail entirely to give engineers any grasp of the true working costs of individual units of crushing equipment, or of the economic merits of innovations and improvements introduced. The variety of methods of accounting as practised on different mines, and the more or less arbitrary entries of expenses in accounts where they do not belong, make it practically impossible to get at really significant figures. For instance (during the transition stage in 1909), the books of one of the amalgamated mines of the East Rand show an amount of £2497 4s. 5d. under 'sundries', while at the same time another mine of about the same size is debited with only £12 3s. under the same heading. More significant detail and greater uniformity are desirable.

Mining expenses and development redemption are most variable factors in individual mining ventures. Their inclusion in the working costs brings a factor of great uncertainty into the statistics, rendering them useless for monthly comparison. Would it not be better (as is the practice in many

## CAPITAL EXPENDITURE

The ease with which money is forthcoming on the Rand for new innovations and inventions—if boomed enough—is no inducement to responsible engineers to pay any more respect to the reservoir of 'capital account' than that due to a waste-paper basket. At one time, however, W. A. Caldecott was very anxious about the question of economy in capital expenditure. In heralding the revolution which the 'New Metallurgy' would bring about in Rand practice, in 1910,<sup>5</sup> he said: "This capital expenditure is likewise reduced by the addition of such crushing units as tube-mills at half the cost or less than the equivalent even in heavy stamps." The metallurgical advisers of the East Rand, faithful believers in the new gospel, made Sir George Farrar say at the March meeting, 1910, that it was expected "to crush with 440 stamps more than now with the whole 820 stamps with consequently much decreased costs." At the time when enthusiasm as to Mr. Caldecott's discovery was at its highest, we were led to believe that all that was necessary was to use coarse screens in the battery, and to buy so many tube-mills, at so much per dozen, to reap the promised profits.

other mining centres) to exclude mining and development expenses altogether from monthly statistics, and to keep separate suspense accounts for them, to be balanced up yearly or half-yearly? This method leaves the management a free hand for a more efficient disposition of underground work. One month is evidently too short a time for the apportioning of costs of underground work. Mining and development expenses are not items suitable for monthly discussions by shareholders. They should be considered in connection with the position of the mine in general, of reduction costs, grade of mill ore and ore reserves, and discussed at longer intervals on the basis of comprehensive interim reports issued by the Board. These reports should explain the actual position and outline the policy to be adopted in the near future.

Mining and development costs apart, the purely industrial reduction costs are fairly constant all over the Rand, depending exclusively on the economical efficiency of the reduction work and reduction management. There exists some diversity in the apportioning of the general charges, which in some mines are to a larger extent included in the various items of working costs, but the general result, which shows about 1s. per ton higher working costs for the 'progressive' mines, can be taken as fairly representing the true position.

By the irony of Fate, only one year and a half later it was Mr. Caldecott's privilege to discover that the capacity of the cyanide works at the East Rand was inadequate to deal with the increased proportion of slime, produced by the score of tube-mills.

For technical purposes, the accounting of an industrial concern may be carried out with one of two ends in view. It may give a clear insight into all details of working costs and capital expenditure, so as to enable those who desire true progress to judge new inventions and innovations on their economic merits. It may conceal blunders and failures. In either case, with very few exceptions, the annual reports give no details of the distribution of capital account and expenditure over the various units of the reduction plant. Consequently the amount of money spent in forcing the 'New Metallurgy' on the old plants cannot be even roughly estimated; but the figures in Table IV are quite good enough to give an idea as to how far the promises of a reduction of capital expenditure "at half costs or less" have been fulfilled.

## FUTURE POSSIBILITIES

In order to prevent any misunderstanding, I want to make it quite clear, that in emphasizing the better economic ef-

<sup>5</sup>Jour. Chem., Met. & Min. Soc. of S. A., April 1910.

ficiency obtained with the sounder and older methods, I am far from advocating a policy of stubborn conservatism, or preaching a dogmatic and definite doctrine of single-stage stamp crushing. On the contrary, I think multiple stage crushing should be practised in every rationally designed plant, so as to realize the advantages derived from intermediate classifiers. The use of tube-mills, for the purpose of grinding, is not in question, but rather their abuse. The abuse consists in transferring to them that part of the crushing work which can be more efficiently done with stamps. It has been proved experimentally that the mechanical crushing efficiency increases with the coarseness of the battery mesh, and it appears that even a screen as coarse as 4-mesh is not the limit of highest efficiency. However, the advantage of a high amalgam extraction, got by double amalgamation, before and after tube-milling, is so marked, that to forfeit this advantage by crushing so coarsely that the mill plates have to be discarded, is not advisable, unless the extraction in the cyanide works can be materially raised above the present level of 85 or 90%. The use of fine

noni Consolidated) is to be reground by the tube-mills, which will work at a high efficiency, because the 40 coarse-crushing stamps will provide them with the right amount of coarse material to produce the most suitable mixed feed. A high amalgamation extraction will be secured by double amalgamation of the mill pulp produced by the 180 fine-crushing stamps, before or after tube-milling.

My remarks against the wisdom of the all-sliming policy refer exclusively to Rand ore and actual Rand practice, and may, under altered conditions, be reconsidered. Another case in which all-sliming may prove to be advantageous, is in adding free cyanide at the head of the tube-mill. H. F. Marriott<sup>6</sup> said in this connection that it had been demonstrated satisfactorily to those responsible for their system, that the gold in the ore passed into solution so readily during its normal course through the tube-mills, that there was not enough left undissolved to make it worth while to continue any subsequent treatment. This he (Mr. Marriott) believed had not yet been demonstrated on a practical scale on the Rand, but if it should prove only partly correct, and it

TABLE V

screens will, therefore, be advantageous, even at the cost of a possible loss in mechanical efficiency. With classifying well carried out, the suitability of the type of tube-mills adopted as a standard on the Rand is doubtful. Other crushing machines may prove more efficient and should be given a trial. It is to be hoped that the tests of the Hardinge mill, now going on under the auspices of the Central Mining & Investment Co. at the Village Deep, will be more thorough and exhaustive than those of the Nissen stamp recently carried out by the same company. A. E. Crosse's regrinder (a drum revolving round a central axis with sliding mullers inside) also warrants testing and holds out promising prospects.

A great fuss was made when it became known that the New Kleinfontein company is deciding upon an increase of capacity of their reduction works, in order to deal with a further quantity of 10,000 tons per month (25% increase) had gone over to stage crushing. The methods adopted, on the advice of the consulting engineers—progressive in their conservatism—are, however, in no way a negation of their policy as hitherto practised, but only a logical combination of both methods in perfect accordance with theory. Of the 220 stamps only 40 will be made responsible for the increase of output. These will crush through the coarsest screens, while the remaining 180 stamps will crush, as hitherto, through fine screens. The underflow of the total pulp (run into classifiers of the type successfully adopted at the Be-

were found possible to effect satisfactorily the rearrangement of solution circuits, it would eventually lead not only to a modification of our great cyanide plants, but probably to a tandem tube-mill and the doing away with the cyanide plants altogether.

The investigation of this question was contemplated in connection with the Giesecke mill tests, but unfortunately, from commercial considerations, they were dropped, on the ground of the non-fulfilment of the expectations of mechanical efficiency. The above figures refer to the two principal units only. Spare tube-mills and other expensive innovations, such as filter-tables and vacuum-filters, are in no way taken into consideration.

CONCLUSION

The bare facts, revealed by the annual reports of our largest producers, show that all this enormous capital expenditure, which has not even yet ended, has only increased reduction costs. The actual results, far from fulfilling those promised, fall short even of those obtained five years ago, if due allowance is made for the progress attained in directions which have no direct connection with the 'New Metallurgy'. The figures, published in Messrs. Denny's paper on the extraction percentages obtained at that time on mines of the Central Rand, with battery pulps as coarse as 20 mesh, leave no room to doubt that the East Rand Mines

<sup>6</sup>Bull. Inst. Min. & Met., 81, June 1911.

could at once reduce their reduction costs considerably by simply returning to the sounder economical methods of the older days. There is no earthly reason to prevent this mine and the Crown Mines reaching an economical efficiency equal to that of the New Kleinfontein mine, which is run on old-fashioned lines without any tube-mills at all. The much abused excuse that the different nature of the ore is responsible for the poor results obtained is hardly borne out by the records filed at the reduction offices, and if any considerable prejudicial effect of this kind were proved it would yet be more than balanced by the advantage of the enormously larger tonnage dealt with.

In face of this array of facts, it would be highly interesting if W. A. Caldecott or F. E. Bosqui, the most prominent exponents of the new school, would explain why it is not desirable to go back a few years, and, with the experience now at our disposal, make a fresh start on the sound basis of actual knowledge gained by the eminently useful research work carried out by the Mines Trials Committee.

## Kirunavaara

By H. V. WINCHELL

\*This mine is in Swedish Lapland, and is called Kirunavaara or Ptarmigan mountain. It has been opened and put in operation during the past ten years under the management of a Swedish 'captain of industry' named Hjalmar Lundbohm. Here within the Arctic circle, north latitude 67°, where the electric lights are started at 2:30 on winter afternoons, are 1200 men mining iron ore for shipment to England, Germany, and the United States. The daily output is about 9000 tons; and it is shipped over a first-class modern railroad in steel ore cars about 100 miles farther north to the harbor of Narvik on the Norwegian coast. Narvik is the most northern ice-free port, and railway station. Here every day in the year iron ore is loaded on vessels at a latitude north of Cape Nome; such is the powerful influence of the Gulf Stream.

The amount of ore in the Kirunavaara has been repeatedly estimated; and each time the estimate is larger. When it is realized that this deposit of hard ore averages about 275 ft. in thickness and is more than two miles in length, and rises in a mountain about 800 ft. above the surrounding country, it may not be so difficult to believe that it contains approximately one billion tons of iron ore.

It is mined in open cuts or terraces; and the blasting can be heard for 50 miles. The annual output of ore now amounts to about three million tons. It is limited by the Government at present to 3,500,000 tons. The Swedish government not only owns one-half of the stock of the operating company, but has an option to purchase the remaining half at an agreed price in about twenty-three years' time.

Although attention has been repeatedly called to this mountain of iron by Laplanders and hunters returning from the far-away northern wilds, yet very little was known about it until the Swedish Geological Survey and Mr. Lundbohm camped there and collected material for reports. The first visit was in 1875 and the second in 1896. Situated about 145 kilometres north of the Arctic circle, 300 kilometres from Lulea on the Baltic, and 170 kilometres from Narvik, the distance from Stockholm is 1413 kilometres, or about 850 miles. The first work preparatory for mining was in 1898. In 1899 the railroad (owned by the Government) reached Kiruna, and in 1902 was built to Narvik. Shipments began in 1903 with a production of about 800,000 tons.

Kiruna is situated in a desolate country, uninhabited before mining began, and only periodically visited by the nomadic Laps, for hundreds of years the only dwellers in the district. The climate is severe, the yearly average temperature being 30° F. Winter lasts from the first of

October to the end of May, and the snowfall is heavy. Kiruna is now a well-built town of about 7800 inhabitants. An electric railway carries the miners to the foot of the mountain, and covered tramways or inclines take them up to the working faces. Hitherto the work of quarrying the ore has not been attended by any unusual problems, but as depth increases and the amount to be mined becomes more nearly equal to the tonnage of ore, there will be an opportunity for the display of engineering skill of a high order. The average dip of the ore is about 55° to the east, and the foot-wall rock as well as the hanging is already being mined in considerable quantity.

The ore is massive and dry, and the rocks above and beneath are likewise solid and fresh crystalline rock. Hence, the ground stands well and only an occasional pillar is needed even in large excavations. The grade of the ore is high. Indeed, these Swedish ores constitute one of the most important sources of high-grade ore in sight today. The chief impurity is phosphorus in the form of apatite. This, however, is so plentiful that instead of being detrimental it becomes an important asset. By the use of the Thomas-Gilchrist process the phosphorus is saved and converted into phosphoric fertilizer. Indeed, the Germans pay about as much for a unit of phosphorus as for a unit of iron. The ore thus far produced from this far northern mine has averaged as follows:

Grade.	Tons.	Fe.	P.
A .....	1,141,302	69.63	0.024
B .....	67,387	69.25	0.67
C .....	371,854	68.60	0.162
D .....	7,003,158	62.48	1.88
F .....	278,966	59.34	2.78
G .....	708,636	57.77	3.09

The amount of titanite acid in the ores is generally less than 0.5%, and the sulphur averages 0.05% or less.

But little is known concerning the geological age of the Kiruna ore and the surrounding sedimentary and igneous rocks. They are presumed to be pre-Cambrian and post-Archean. The geology of the ore deposits is complex and most interesting, and has been made the subject of careful study by Messrs. Lundbohm and Geijer.

It is a remarkable fact that the great orebodies of Kirunavaara, and Luossavaara, which lies a mile or two farther north, almost in line of strike, occur between two beds of porphyries of rather acid composition. The foot-wall consists of syenitic rocks with a silica percentage of about 60, the hanging wall of quartz porphyries with about 70% silica. The quartz porphyry is interwoven with innumerable dikes of finely crystalline apatite, generally small, but sometimes more than one metre in thickness. These dikes are often rich in magnetite and hematite. They also often contain much tourmaline and sometimes quartz and albite and show flow structures and orientated intergrowths. The quartz porphyry on the eastern side of the ore also contains numerous fragments of magnetite similar to that in the iron mountains. No dikes of magnetite are found cutting the quartz porphyry; but many intersect the syenite on the west. The contact between ore and country rock is generally sharp and distinct. The ore chiefly consists of magnetite, but contains hematite in small irregular lumps, in isolated crystals, and in small veinlets. The ore is sometimes laminated and intimately banded with alternating layers of apatite. Some geologists have mistaken this structure for evidences of sedimentary origin.

According to the two main theories, this ore is either pneumatolytic-hydrothermal or magnetic. It occurs in a series of bedded eruptives; is younger than the underlying syenite porphyry and older than the overlying quartz porphyry. It was, therefore, formed either by gaseous emanations from the older rocks during an interval or pause in the outpouring of solid eruptive matter, or is an actual eruptive sheet or dike of magnetite from an acid magma. In either case it is a deposit of rare type and phenomenal importance. I have purposely refrained at this time from advocating either theory.

\*From a report on the Stockholm meeting of the International Geological Congress, made to the Minnesota Academy of Science.

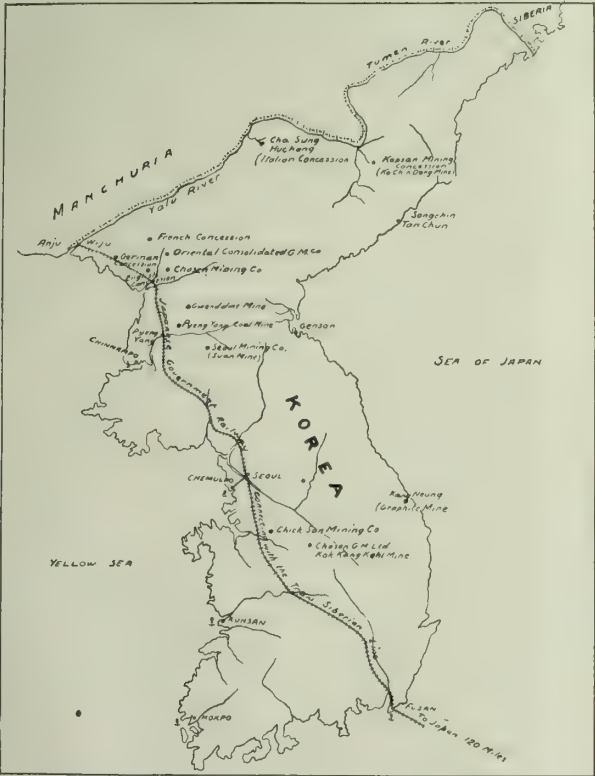

Gold Mining in Korea

By J. D. HUBBARD

The Oriental Consolidated Mining Co. still holds first place in Korea as to output. For the fiscal year ended July 1, 1911, the company mines produced 344,097 tons of ore valued at \$5.19, or \$1,787,628. The total receipts for the year were \$1,541,347; total operating costs \$839,857; and the operating profit for the year was \$701,488. On new construction and development work, \$28,768 was expended. The net receipts over all expenditures for the year were \$672,720, and the surplus was increased from \$532,791 to \$561,426 during the year. From the granting of the concession to 1912 the company has produced over 2,600,000

the leaching vats of the old cyanide plant, was put into successful operation. The net extractions by the old percolation treatment have been quite high during the past few years, but unquestionably can be bettered by modern treatment, and the cost of treatment lowered. This concentrate dump retreatment is rather a new departure in cyaniding, and Mr. Drucker's experience will be awaited with interest. The Oriental Consolidated is to be congratulated on this effort to bring the plants up to date. Heretofore the methods used have been antiquated. It must be borne in mind however that this was the first mining company in the Far East to successfully treat low-grade ores, and its pioneering has helped other successful companies in getting started.

Last year this company had much trouble over the matter of cordwood and mine timbers. A large amount of both is required and the company has practically exhausted the visible supply within the limits of its concession. They commenced to cut wood and timbers outside the limits of their concessions, and being perhaps inconsiderate of the rights of other concessionaires, were stopped by the authorities, upon complaint of those trespassed upon. As cordwood and mine timbers are necessary for the operation of gold

PRINCIPAL MINING CONCESSIONS, KOREA.

tons of ore, valued at over \$16,000,000. Alf Welhaven is general manager in Korea, G. M. Ford is general superintendent, and A. E. Drucker consulting metallurgist. During 1911 the company paid dividends of \$644,085 on the net capitalization of \$4,293,900. H. C. Perkins of New York City is president of the company.

The ore reserves on July 1, 1911, were estimated as follows:

Mine.	Tons.	Gold Content.
Tabowie .....	410,000	\$2,000,000
Taracol .....	285,000	1,302,000
Chintui .....	13,000	51,900
Kuk San Dong .....	35,700	79,350
Charabowie .....	47,000	297,000
East Candlestick .....	11,580	124,520
Totals .....	802,280	\$3,584,770

All the mines of the Oriental Consolidated are in good shape, except the Kuk San Dong and Chintui, which are about exhausted of pay ore. The increase in the value of the ore reserves in the other mines, however, offsets the decrease in the Kuk San Dong and Chintui mines.

During the past year the new cyanide plant, designed and erected by A. E. Drucker, at Kuk San Dong for the regrinding and retreatment of the concentrate dumps from

TARACOL HEAD-FRAME, ORIENTAL CONSOLIDATED.

mines, and as the Japanese government has heretofore always encouraged the development of mines in Korea, deriving revenue therefrom, there is no doubt but that the matter will be adjusted to the satisfaction of all concerned. It is unfortunate that the Oriental Consolidated did not do some reforestation many years ago, especially as the ore reserves have always been developed so far ahead as to prove a good life to the mines. It is not yet too late, for the company is still good for many years of productive life.

The Seoul Mining Co., operating mines at Suan, in Hwang Hai Do province, has had another successful year. The 40-stamp mill was completed December 1, 1909, and has been in continuous operation ever since. During 1911, 70,229 tons of ore was crushed (an average of 5.53 tons per stamp per day), from which an average recovery of \$7.85 was made, at a working cost, including development, of \$3.01. This cost is divided as follows: Mining, \$1.25; milling, \$0.62; transportation, \$0.05; concentrate expense, \$0.24; general expense, \$0.85. The mill recovery was \$6.21 per ton; concentrate \$1.62 and from ore sales to the Tacoma smelter \$0.02 per ton. The last item represents an adjustment in 1911 on shipments made in 1910, as no high-grade ore was shipped during the year. The average extraction obtained was 79.1% of the gold and 18.4% of the copper content of the ore, or 69.4% of the total. The greatest loss of copper is in the slime, and investigations

are under way to increase the saving. Microscopic examination has shown that the bismuth is closely associated with the copper and exists in a finely disseminated state, probably as native bismuth.

The ore reserves on January 1, 1912, are estimated as follows:

Orebody.	Tons.	Gold.	Bismuth,		Gross value.	Per ton.
			Copper, lb.	%.		
Eastern ....	191,400	\$10.58	1.3	3.50	\$3,024,000	\$15.80
Central ....	5,000	20.00	3.0	12.00	172,000	34.40
Western ...	15,000	13.50	1.8	4.00	303,000	20.22

The net returns from mining and milling operations for the year was \$339,844. During the year two dividends, of 30% and 15% respectively, were paid, \$20,000 was written off for depreciation, and \$18,000 was expended for directors' fees and administration expenses. The company is capitalized for \$500,000, of which \$400,000 has been issued. The company has the exclusive right to select mining property within the limits of the Suan concession until 1916. Prospecting is now being carried on, especially at Tul Mi Chung, where silver-lead ore occurs; Sang Dei, where gold-copper ore is found; and Paa Whan, where low-grade gold-copper ore occurs. This company has so far paid dividends amounting to \$220,000. The excellent treatment accorded employees of the Seoul Mining Co. has culminated in good results obtained, loyalty and long service rendered. The company looks forward to a prosperous year in 1912. A. H. Collbran is general manager at the mines.

The Chiksan Mining Co., operating a concession in North Chung Chyong Do province, is after many vicissitudes, getting solidly established, and during 1911 a new organization was effected. Formerly the concession was owned jointly by the Korean Exploration Co. and the Shibusawa-Asano Mining Partnership. Under the new organization the Korean Exploration Co. owns 24% of the capital stock, Baron Shibusawa owns 24%, and the Chiksan Mining Co. owns 52%. G. R. Gerry of the American Electric Co. of Yokohama is president, and G. A. Bagnall, of the same company, is vice-president. A. W. Taylor is general manager in Korea, and the directors are W. D. Townsend of Chemulpo, and Messrs. Hillis and Mairabara of Yokohama. The Chiksan Mining Co. is capitalized for Y2,000,000, the par value of the shares being Y50 each. The stock is fully subscribed and the money is in Japanese banks. The stock was practically all subscribed locally, that is in Japan and Korea.

The mining concessions of the Chiksan company comprises an area of about 20 square miles. It is the most conveniently situated of all the mining concessions in Korea as regards transportation, the headquarters at Yangdei being but 9 miles from Seikwan, on the main line of the Korean Central railroad. From tidewater at Tsunpo to Yangdei is but 14 miles. The company expects to erect a central electric power plant at Tsunpo, using coal as fuel, and transmitting power to the different plants.

There are many strong veins on the concession, besides valuable placers. Between Kurangkohl and Sajunkohl there is an orebody 8000 ft. long on the strike and 30 ft. wide, averaging \$5 per ton on the paystreak. Some of the outcrops run up to 80 ft. in width, showing assays of from \$3 to \$5 per ton. There are 75 veins on the concession, besides 1500 acres of placer ground. The placer ground has been prospected and its estimated total value is \$2,500,000. The working costs are estimated at 6c. per yard.

A 150-ft. two-compartment shaft at Sajunkohl is being deepened, and the old Homune mine is being unwatered preparatory to re-opening. The Homune shaft is down 225 ft. Among the native Korean miners the Homune mine is recognized as the standard of wealth. When asked what they think of a good prospect in other localities they will reply "as rich as Homune". Some very rich ore has been taken out of the old workings by Korean miners. The company is rapidly getting its mines in good shape for profitable working. In the Yangdei mill dump is over 10,000 tons of tailing of an average value of \$3.50 per ton. A cyanide plant is now being erected to treat it.

A good timber supply, sufficient for 6 or 7 years, is available 8 miles from Yangdei. The company now has 17 stamps dropping. Up to December 1911, when the new 10-stamp mill was started, the average bullion production was \$8000 per month in gold and \$2000 per month in concentrate, and the clean-up for the year was \$25,000. The concentrate is shipped to Tacoma for treatment. No doubt this company will later treat its own concentrate. Up to the advent of the new 10-stamp mill, 825 tons of ore per month was crushed. This mill was built in Japan. The net profits last year were 33 $\frac{1}{3}$ %. The mills are distributed as follows: Two 5-stamp batteries at Yangdei, also 4 Nissen stamps, and a 3-stamp triple discharge Hendy mill at Kurangkohl. I have been unable to get estimates of the ore reserves for 1912.

One strong new company came into the field during 1911, the Chosen Mining Co. This company was incorporated to take over the interests of the Morris-McGary partnership mining concessions in North Pyeng An Province, Yeng Byen district. J. H. Morris and E. M. McGary, through the native prospectors, obtained the Kosung and Wha San orebodies, among the best in Korea. They did about one year's development work prior to the incorporation, proving the value of the ore on both concessions. The Chosen Mining Co. was then incorporated under the laws of Arizona, for \$50,000 in shares of \$5 each. Two-fifths went to Morris & McGary as the purchase price of the concession, one-fifth is held as reserve, and two-fifths, or 40,000 shares, was sold at par value, \$5. The capitalization of this company is rather low for large operations, but the management has definite plans, and will start moderately and increase the reduction plant from the operating profits. This should insure large dividends, which is the ambition of the management.

In the Kosung mine, the ore reserves on July 1, 1911, were estimated at 150,000 tons of ore of an average value of \$5 per ton. By the end of the year the ore reserves were increased to 300,000 tons. Some of the ore assays very high, up to \$200 per ton, and shows free gold. Practical laboratory tests prove the ore to be free-milling. With such a start and such an ore reserve the Chosen Mining Co. should quickly take its place as one of the important mines in Korea. J. H. Morris of Seoul is vice-president and general manager, E. M. McGary is general superintendent at the mines, and W. F. Perkins of San Francisco is president.

For the past two years the French concession in the Chang Song district, one of the largest in Korea, has been worked by Koreans under the leasing system. The company has derived some revenue from this source, but it leaves the mines in bad shape and is not to be commended. Also the primitive methods of the Korean millmen are wasteful. I have assayed tailing from their mills that contained \$90 per ton. Some intelligent Koreans, who had been trained at the Taracel cyanide plant of the Oriental Consolidated, soon found that the tailing was readily amenable to leaching with cyanide solution, and have been making money ever since. There are many strong and well defined veins on the concession, and some are assaying very high. The concession is also well forested. M. Saultreaul, of Paris, owns the concession and is represented in Korea by E. Martel of Seoul.

Recently the concession has been leased to L. Rondon & Co., of Seoul, for a yearly rental of Y40,000, the lessees to pay all taxes and assume all responsibility for the concession. Also, as in the case with the Chiksan Mining Co., 25% of the net profits go to the government. The lessees have bought the 5-stamp mill of the German concession and will install it at Chang Song. I hope the lessees will get things going in good shape and make a good profit. Although some distance from the railroad the French concession has many natural advantages, and has a larger visible supply of timber than any other concession in Korea except the Chosen Mining Company.

An editorial appearing in the *Mining and Scientific Press* of October 29, 1910, refers to the extra-territorial rights of foreigners as having naturally disappeared. This is true except in one case. The extra-territorial rights of American citizens have not disappeared, nor has any notification to that

effect been given by the American Consul-General in Seoul. As I understand the treaty, one year's previous notification must be given. It should be understood, however, that all the American citizens now resident in Korea are only too anxious to preserve Japanese authority, and in several cases recently have voluntarily submitted to the local authority to facilitate good relations. Foreigners may obtain mining concessions in Japan proper now, as the Oroyo-Brownhill syndicate did last year. And mining promotion is far from a standstill in Korea, as the three latest companies to organize the Seoul Mining Co., the Chosen Mining Co., and the Chiksan Mining Co., have all been financed in Japan and Korea. The investing public in the Far East is ready at all times to buy good mining stocks, and many more good mines will yet be financed here.

Korea is far ahead of Japan in gold production. According to an official report, the total amount of Korean gold exported during the first half of the year 1911 was Y6,350,140. During the same period gold ore in addition to the value of Y119,422 was exported. The total amount of gold produced in Korea during half a year is greater by over Y300,000 in value than the annual output of Japan. The Korean miner is probably the best native miner in the world, all considered, and he seems to take to mining naturally. Prospecting is active and the Mining Bureau receives numerous applications from foreigners, Japanese, and Koreans. There are many virgin goldfields in Korea yet, and I think there will be a mining boom here when the facts are known.

## Western Mining Districts

The United States west of the 103rd meridian, comprising the Rocky Mountain, Plateau, Desert, and Sierra Nevada regions, is one of the most important producers of precious and allied metals in the world. In this area are many mining regions or camps, which are known as 'mining districts.' In most of the states the boundaries of these districts are well recognized and some of them are legally recorded, and nearly all can be plotted on state maps with a fair degree of accuracy. In the Mother Lode country of California, however, there are no 'mining districts' in the sense that the term is used in the other states.

The output of the mines in the United States is reported yearly to the division of mineral resources of the U. S. Geological Survey, and by a study of the district reports for a number of years the values of the most important metals produced in each district can be fairly well determined. In some districts, notably those in Colorado, the values of several products are nearly equal, but in most of the districts the output of one metal has a greater value than of the rest.

The U. S. Geological Survey has published reports on the economic geology of a large number of the mining districts of the country. In 1908 the Survey published in its annual volume, 'Mineral Resources of the United States', a map of the Western states showing the position of the mining districts. Bulletin 507, 'Mining Districts of the Western United States,' which contains a revised edition of the original map, together with much new material, is an index of the gold, silver, copper, lead, zinc, quicksilver, iron, and rare-metal mining districts of the Western states.

A geologic introduction to this report, by Waldemar Lindgren, not only gives a general summary of the geology of the states, but also describes in some detail the economic geology of the more important districts as well as some of the less widely known mining regions. This part of the report includes a small map of the Western United States showing the general distribution of the mining districts. The report contains 14 state maps, which show the position and area of over 1400 mining districts. The map including the largest number of districts is that of the northern counties of California, which contain 222 districts; the smallest is the map containing that of trans-Pecos Texas, which shows only 11 districts. With every mining district

symbol on each of these maps is a number which refers to its name in an accompanying list. A bibliography of the publications of the U. S. Geological Survey on each district is included in the text, as well as a condensed statement of the geology and nature of the ore deposits, a list of the metals produced, and the shipping point of the camp.

The bulletin contains the latest available information, but the Director of the Geological Survey desires that any mistakes or omissions be brought to his attention by men in the field who are in a position to aid in this work.

## Tuolumne Table Mountain

By AUGUSTUS LOCKE

Near Jamestown, California, the important Mother Lode veins stand up in a low ridge. On this ridge lie the Harvard and App mines. North of the town, the ridge buries itself beneath Tuolumne Table mountain. It will be recollected that Tuolumne Table mountain is a lava-cap of a Tertiary river course, brought out to its present relief by the depression of the adjacent land surface. The top of the mountain

CROSS-SECTION, TUOLUMNE TABLE MOUNTAIN.

is essentially uneroded, and is remarkably flat. An interesting condition is the stepping up of the mountain immediately southwest of the place where it crosses the quartz-bearing ridge. The 'rise' is covered by debris; in the volcanic rock, no fault materials are visible. But the large facts indicate definitely enough that a displacement of 50 ft. or so in the plane of the gouge shown in the accompanying section has taken place since the solidification of the lava, and since, therefore, the formation of the quartz. The immediate cause of this displacement may have been the expansion of the foot-wall serpentine. In a general way, the fact that the portion of the mountain which is above the serpentine is rougher than that above slate suggests that the serpentine has been moving.

## Queensland Gold Production

The yield of gold in Queensland for April shows an increase, compared with that for April 1911, of 3720 oz. fine in quantity and £15,801 in value. The total output for the month was 30,689 oz., valued at £130,358. The improvement shown in the return is all the more satisfactory, inasmuch as it is spread over several fields. Thus, at Croydon there was an increase of 831 oz.; at Cloncurry, 110 oz.; at Etheridge, 356 oz.; at Mount Morgan, 2173 oz.; at Ravenswood, 1209 oz. At Charters Towers there was a decrease of 330 oz., and at Gympie of 344 oz. The yield for the first four months of the present year was 109,389 oz., of the value of £466,354, a decrease, when compared with the corresponding period of last year, of 3646 oz. in quantity and £15,487 in value.

ANIAK is the name of the district to which the most recent Alaska stampede is directed. The discoveries are along Marvel, Fisher, Cripple, and Dome creeks, tributaries of the Kuskokwim river.

## Marble Deposits of the Inyo Mountains

By ROBERT T. HILL

These marbles occur on the southwest side of the White Mountain Inyo range, a parallel range to the Sierra Nevada, lying to the east of Mount Whitney and separated therefrom by the Owens River valley, in Inyo county, California, directly alongside the Southern Pacific railroad, and on the east shore line of the Owens Lake basin.

The White Mountain range is one of peculiar geographic and geologic interest. It may be said to be the last and westernmost of the desert ranges of the Nevada type, and the first of these ranges east of the great eastern escarpment of the Sierra Nevada of California. The range has a northwest-southeast direction, and is the surviving remnant of ancient rocks which were folded in a similar direction. The material of the mountains is altered, folded, and faulted sedimentary rocks of the older or lower half of the geological column, which have undergone regional metamorphism into quartzites, slates, and marbles; accompanied by occasional small dikes of basic rocks, cutting across the folded strata, and apparently a large extrusive mass of the late Tertiary volcanic rocks, seen just east of Lone Pine station, which constitutes the northwestern end of the marbleized block. Proceeding from northwest to southeast, the marbles are seen outcropping from a distance of six miles along the southwest, or Owens valley, side of the range, from three miles northwest of Inyo station to a mile and a half southeast of Swansea.

*Geology.*—In the '60s the area was reconnoitred by Mr. Brewer of the California (Whitney) Geological Survey, who found a single fossil in the rocks of the White mountains, from which he reached the deduction that they were of Jurassic age. This fossil, however, was a cephalopod, which in those days prior to the era of rock cutting and polishing was a very unsatisfactory criteria for determination. In another year the area was visited by G. K. Gilbert, who pointed out, in his brief notes, some of the interesting structural features. In 1894 C. D. Walcott made several reports of the White and Inyo Mountain ranges, and gave sections showing the existence of a great thickness of Cambrian and other succeeding Paleozoic rocks, and pointed out the facts of their Appalachian structure.

The rocks of the range are bands of strata which have been folded into anticlinal arches, the axes of which are parallel to the trend of the range. The limestones of this locality were marbleized during the Appalachian mountain period, when they were folded and the beds of marble all co-extensive with certain well defined strata now tilted at various angles in harmony with the faults. Subsequent earth movements have fractured and faulted these layers, dislocating them sometimes vertically, sometimes horizontally. The effect of these later movements is variable. In some areas they shattered the ancient marbleized strata into minute blocks, in others the small fracturelets thus created have been re-cemented and solidified with mineral oxides, producing the effects of color which gives to the marble in places the peculiar beauty which renders it of great artistic and commercial value. Other large areas seem unaffected by this cross-faulting. The important fact concerning this structure is that the marbleization is ancient and general, and took place in the older geologic periods mentioned, and is not local or spotted, as is found sometimes adjacent to recent fault lines. The marbleization itself is homogeneous and thorough.

*The Marbles.*—The marbles outcrop the entire distance previously mentioned, except for a short interval occupied by a stream valley just east of Swansea, but are not in continuous line on account of east-west faults which have thrown them back and forth in horizontal blocks or massive hills, as elsewhere mentioned. In places these faults or fault-zones result in many cross-fractures, so that the material is very much shattered at the surface. In other places, however, as at the Inyo quarry and at Swansea,

the marble is found in blocks or squares of large dimensions, and there seems no question but that the blocks of any workable size desirable may be found in abundance. This is especially true about a half mile east of Swansea, where the white marble stands in vertical strata and is unshattered, and where, owing to the verticality of the strata, it can be quarried to a depth with a certainty of continuity.

At Inyo only has commercial quarrying been conducted and from this locality much material has been taken in times past which has been used in various structures in San Francisco, Los Angeles, Stockton, and other places. There are several openings in the southwest slope of the hill, one of which produces marble of a pure white, and two others which yield a variegated product. These quarries are within a quarter of a mile of one another. Two of these quarries are situated from two to three hundred feet above the valley plain and are equipped with tramways and cranes for quarrying, but of a type which can be replaced to advantage by more modern facilities.

*The White Marbles.*—The white marble quarry lying to the northwest apparently has an inexhaustible quantity of material, which if properly quarried can be obtained in blocks of any desired size. The quality is the purest white, fine grained, and, as stated by G. P. Merrill, "equal in texture to Italian marble, but much harder, firmer, and more compact." It is certainly handsomer and purer white than any American marble with which I am acquainted, and this fact alone should render the material of great value. These white marbles are singularly free of what has been termed the 'skim-milk blue' which characterizes all of the graphite-tainted marbles of the Eastern United States.

*The Colored Marbles.*—Geologically the variegated marbles at the quarry a short distance southwest of the white marble quarry, are a continuation of the same stratum and are of the same substance, which has been variegated by the addition of the coloring mineral oxides of manganese and iron, which have been introduced through the transverse fissures. G. P. Merrill may be again quoted: "In texture this is of the same quality as the last, but the white ground-mass is injected in every direction with blotches, streaks, and finely divided branching, feathery dark brown, nearly black, dendritic, or fernlike markings—and which, added to occasional blotches of sienna yellow, produce an effect that must be seen to be appreciated. Still a third variety is sienna yellow of varying shades. This last, while nearer the true Italian sienna than any now produced, differs in being distinctly granular in texture, and can be more correctly compared with the well known Estromoz or so-called Lisbon yellow, from Alemtojo province, Portugal."

*The Blue Marbles.*—There is still another type, which produces a radically different but nevertheless desirable group of colors. About a mile north of Inyo and also north and east of Swansea, there are vast outcrops of marble of the black variety—apparently representing an ancient stratum adjacent to that of the white marble, and probably below it in geological sequence. Here may be seen a vertical exposure of several hundred feet of thick bedded strata, of a dark-blue color, in most places homogeneous and even in texture, but presenting among the others one thick bed in which the blue matrix is studded with white, oval bodies, suggesting the blue and white effects used by the makers of Wedgewood pottery. The entire material is thoroughly calcified and dolomitized into massive stones. The whole gamut of blacks is to be found here, blue-blacks, the gray blacks, and the pure black marbles, in unlimited quantities, and can be gotten out in blocks of any desired size.

*Extent and Quantity.*—The quarries which have been opened, as above described, represent only a fractional portion of the material, which extends both to the northwest and southeast for several miles, and which has been undeveloped. The southernmost point examined, some three miles south of the Inyo quarries, and about a half-

mile southeast of Swansea, shows a magnificent vertical stratum of the pure white dolomite marble, estimated to be over 100 ft. thick and which has an indefinite depth. The white marble beds extend from here to northeast of Inyo, some three miles, but they are much shattered by cross-faulting at the latter point. Concerning the quantity of the marbles, there can be no doubt but that it is ample for development.

## Determination of Small Amounts of Platinum

By F. P. DEWEY

In the regular course of assaying for the precious metals, gold is parted from silver by dissolving the silver in nitric acid. If platinum be present in small amounts only, it will readily go into solution in the nitric acid. If now a limited amount of hydrogen sulphide be added to the solution from parting, any platinum present will be precipitated as sulphide, along with some silver sulphide. On filtering off the precipitate (which generally is sufficiently washed by the operations necessary to transfer it from the precipitating-dish to the filter), the moist filter is transferred to a small porcelain crucible, dried at a low heat, and burned off by gentle ignition. This transforms the sulphide precipitate into a metallic sponge, which is wrapped in a small piece of thin lead foil and cupelled. The resulting bead is then parted in strong sulphuric acid, when the platinum will be left as a dark residue, generally collected in spongy form, even when minute in quantity. This sponge, after reboiling in fresh acid, if necessary, is suitably washed by decantation, annealed, and weighed.

Generally, the final metal speaks for itself as being platinum, but if there should be any doubt, it may be dissolved in a drop or two of aqua regia and gently evaporated. The solution obtained may be tested with potassium iodide, or a few small crystals of ammonium chloride may be added, when the characteristic precipitate will show itself. As a further test, this may be filtered off and gently ignited to produce spongy platinum. If the amount of the final metal be considerable, the platinum may be determined by the double-chloride method. Any decided difference shown would indicate the presence of other members of the platinum group, for which direct test could then be made.

For precipitating the platinum and the necessary silver from the parting solution, a very dilute solution of hydrogen sulphide should be used. One part of a strong solution should be diluted with from 10 to 20 parts of water. If the solution of silver nitrate be strongly acid, it should be largely diluted, or it may first be evaporated and then diluted. The very dilute hydrogen sulphide solution should be added very slowly to the silver nitrate solution with constant stirring. The solution is, of course, at once darkened, but there should be no immediate separation of a visible precipitate. The solution should be stirred occasionally, and in about 2 hr. flocks of precipitate should appear. It may be filtered in from 3 to 4 hr., but it is a good plan to let it stand over night if possible.

The amount of hydrogen sulphide required depends, of course, upon the amount of platinum present. If this should be roughly known or suspected, the amount used should generally be enough to precipitate the platinum and from three to five times as much silver. On an entirely unknown ore, I should at first use 1 c.c. of strong hydrogen sulphide solution diluted to 15 c.c., and reserve the filtrate from the sulphides for re-treatment if necessary. On an unknown bullion, I should use 2 c.c. of strong solution diluted to 30 c.c., partly because bullions are liable to carry much more platinum than any ordinary ore, and partly because the volume of the silver nitrate solution from parting the gold must necessarily be larger. If, however, it is known that minute amounts of platinum are

present, it is still necessary to use sufficient hydrogen sulphide to give a silver bead large enough to handle comfortably. For this reason, I seldom use less than the equivalent to 1 c.c. of strong hydrogen sulphide solution.—(From the *Bulletin*, Amer. Inst. Mining Engineers.)

## Estimation of Sodium Peroxide

By H. L. EASTON

The following method for the estimation of sodium peroxide was devised by J. P. Walker as a modification of the method given in Sutton's 'Volumetric Analysis,' and has been slightly modified by myself.

*Preparation of Solution.*—A N/10 solution of  $K_2Mn_2O_8$  contains 3.16 gm. to 1 litre of water. Standardize such a prepared solution with 0.250 gm. of oxalic acid ( $C_2H_2O_4 \cdot 2H_2O$ ). By comparison of equations for the oxidation of  $C_2H_2O_4$  and Fe by  $K_2Mn_2O_8$ , it will be seen that the same quantity of permanganate is required to oxidize one molecule (126) of oxalic acid as is needed to oxidize two atoms (112) of Fe. Then, if 0.250 gm. oxalic acid was taken, the proportion is:

$$126 : 112 :: 0.250 : X \quad (0.222)$$

That is, 0.250 gm. oxalic acid = 0.222 gm. iron.

Say, for example, it is found by titration that it takes 40 c.c. of the permanganate solution to oxidize 0.250 gm. oxalic acid. Then 0.222 divided by 40 = 0.0055.

$$1 \text{ c.c. } K_2Mn_2O_8 = 0.0055 \text{ gm. Fe.}$$

according to the reaction:

$$(A) \text{ or } 316 K_2Mn_2O_8 = 390Na_2O_2$$

Also according to reaction:

$$(B) \quad 316 K_2Mn_2O_8 = 560 Fe$$

Then by (A) and (B)  $560 Fe = 390 Na_2O_2$ .

It results that 1 c.c. permanganate solution equals 0.0055 Fe.

$$\text{Then } 560 (Fe) : 390 (Na_2O_2) :: 0.0055 : X$$

$$1 \text{ c.c. } K_2Mn_2O_8 = 0.00383 \text{ gm. } Na_2O_2$$

*Process.*—On account of the hygroscopic character of sodium peroxide it is practically impossible to get an accurate average sample for analysis. To surmount this difficulty, three or four samples are taken from different parts of the can or bottle, analyzed separately, and their results averaged. This procedure will give a fairly accurate estimate of the percentage of the sodium peroxide in the product.

After shaking well the can containing the peroxide to be analyzed, take out, with a clean dry spatula, 15 or 20 gm. and transfer to a clean dry weighing bottle. In taking this sample, dip the several portions composing the 15 or 20 gm. from different parts of the can, the object being always to get as nearly an average sample as possible. Take three or four such general samples, using as many weighing bottles, and shaking can well after taking each. Do not leave the peroxide, either in the can or the bottles, exposed to air longer than absolutely necessary.

From the weighed bottle take out from two to three grams of the peroxide on the end of a dry spatula and drop it into a flask containing some 400 c.c. of a previously cooled solution of 20%  $H_2SO_4$ . Wash off spatula with water jet, close flask, and shake well. While the sodium peroxide is dissolving, weigh bottle again to ascertain exact quantity taken for analysis. Dilute contents of flask to a litre and with a pipette draw out 100 c.c., deliver into smaller flask, and titrate with the permanganate solution until pink color does not disappear by shaking.

The number of cubic centimetres of permanganate used, multiplied by the value of the permanganate solution in

terms of sodium peroxide per cubic centimetres multiplied by ten, gives the grams of peroxide in the weighed portion. This multiplied by 100 and divided by the accurate weight of the peroxide used for analysis gives the percentage of sodium peroxide. Treat each sample taken in like manner and average the results. If the available oxygen is required, multiply the percentage of sodium peroxide obtained above by the factor 0.205.

## South Dakota Metal Production

The total value of the production of gold, silver, and lead in South Dakota for 1911, as reported from 37 productive mines, 17 of which were placers, amounted to \$7,550,758, according to C. W. Henderson of the U. S. Geological Survey. This yield is only slightly below that of the record output in 1908, and when compared with the value of \$5,467,031 in 1910, shows an increase of \$2,083,727. The gold output was 359,903.90 fine oz., valued at \$7,439,874, almost 99% of the total value. The increase in gold for the year was 98,569.72 fine oz. in quantity and \$2,037,617 in value. The yield of silver also increased from 118,800 to 203,755 fine oz. Smelting ore from South Dakota in 1911 carried 64,311 lb. of lead, against 14,136 lb. in 1910. Placer gold increased from 143.77 fine oz. in 1910 to 584.03 fine oz. in 1911.

A total of 1,946,127 short tons of ore was mined and

treated in 1911, compared with 1,523,929 tons in 1910. Of this total, 1,940,661 tons was treated in the mills of the state, yielding as bullion \$7,317,942 in gold and 172,598 fine oz. of silver, valued at \$91,477, with an average recovery per ton of \$3.77 in gold and 5c. in silver. Smelting ore, 5466 tons, averaged 0.959 oz. of gold per ton and 5.69 oz. silver.

The gold mines of the Black Hills, chiefly in Lawrence county, were steadily operated in 1911, and in addition there were a few productive mines not operated in 1910. The Homestake mine, which produces most of the gold bullion from this state, at the beginning of the year had completely overcome the labor difficulties of 1909-10 and was again operating at the full capacity of its plant of 1000 stamps. Developments of note in the northern Black Hills were the advancement toward completion of the Homestake hydro-electric plant; the building at Galena of a new smelter and the Gilt Edge-Maid concentrating plant; the proposed construction of a roaster at the Golden Reward mine to handle the newly developed sulphide ores; the open-cut mining and continuous operation of the Wasp No. 2. Co.; and the building of the 300-ton cyanide plant of the Bismarck company. In the southern Black Hills the first dredge to be built in the state was operated for 5½ months at Mystic, Pennington county. The dredge is owned by the Castle Creek Hydraulic G. M. Co., and has close-connected buckets of 5-cu. ft. capacity.

## Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

### A Mountain of Gold

The Editor:

Sir—Referring to my article under this title published in your issue of December 2, 1911, I have now obtained a photographic print of the biggest mass of silver ever mined. This I owe to the courtesy of D. W. Brunton. This mass of silver came from the Smuggler mine, at Aspen, weighed 1840 lb., and was of a purity equal to sterling silver. Such impurities as were present consisted of rock. It came from a small lenticular body of

MASS OF SILVER, SMUGGLER MINE.

native and sulphide silver ore, ranging in thickness from 2 inches to 2 feet, that yielded in all nearly 10 tons, sold for a trifle over \$90,000. It was part of the same deposit of high-grade sulphide and native silver ore that was found in the Mollie Gibson, although the two orebodies were widely separated by a fault.

T. A. RICKARD.

London, June 20.

### The British Language

The Editor:

Sir—In your editorial on the British language in the issue of March 9, 1912, the sentence in parentheses, “(The Horse-Shoe and Ivanhoe lodes are frequently disturbed by slides)”, is mine. “Lode disturbed by slide” is from the mine cable to London. I just wished to point out this feature of these two mines. Yet, I quite agree with your comment on the word ‘slide’, and will use the correct word, ‘fault’, in future.

In mixing with miners and millmen some peculiar phrases are heard. In West Australian mills, especially the roasting plants, a great quantity of sulphates are precipitated from the circulating waters in pipes, pans, agitators, and the like. This forms a hard slaty scale, which is easily removed. The men invariably call this corrosion. Why, I do not know; and I have often explained to them that when corrosion goes on, something is being eaten or worn away. Scale is as handy a term for this material as can be found. Tautology is heard all day long, whether

at work or in town. The term ‘running’ is commonly used in a mill. The engine, crusher, battery, pan, tube-mill, or pump is ‘running.’ Why not working? Also, the solution ‘runs’ down the launder, or the pulp then ‘runs’ to the agitator. Why not flows? Men and animals run, not liquids.

“When do you reckon to get going?” is often heard in reference to starting a new plant, or any particular machine which may be under repair.

I am glad to say that few of the men I meet use the plural on slime, sand, concentrate, or middling. A collective noun of this type requires no ‘s’ to indicate the plural; besides, it sounds better without. The drive-ropes on an engine are often spoken of as ‘cables.’ Ropes is the correct term. One speaks of ship’s cables, and sometimes cables for transmitting electric power. In one dry-crushing plant in which I worked, everybody, from mill manager down, spoke of the dry-crushed ore as ‘pulp.’ “The pulp-bins are nearly full.’ Why not fine-ore bins? I never used the term, but could not break anybody of the habit; in fact at first my use of ‘fine ore’ was not understood. A mixture of water or solution with crushed or ground ore, I call pulp. Nothing else.

‘Re-precipitation’ has always been a mystery to me. Why the ‘re’? This means again. Nothing has been precipitated again. If a solution has dissolved the gold from the slime in an agitator, or other machine, and through some cause there is a loss of gold, this has not been re-precipitated, but simply prematurely precipitated, before it reached the precipitating-boxes. These are a few local failings not mentioned in that useful little book, ‘A Guide to Technical Writing.’

KALGOORLIE CORRESPONDENT.

Kalgoorlie, May 6.

### Free Use of Timber From Public Lands

The Editor:

Sir—In the issue of June 22, Ernest V. Orford criticizes as erroneous a ‘Concentrate’ item on use of public-land timber which was taken from my book on mining law. The public-land laws regarding the use of timber are as much of a ‘hodge-podge’ as some of our other public-land laws have become since the radical conservationists of the East and the sane (?) conservationists of the West began pulling in opposite directions. My statement was prepared from some experience and from close association with those engaged in overseeing the use of public-land timber, both in the field and at Washington. Therefore, I consider it very accurate, notwithstanding that it varies somewhat from the interpretation of Mr. Woodbury. A new set of timber regulations relating to Alaska was drafted last winter. These will not really alter the old conditions, only reduce to some extent the amount of timber allowed. This is strictly ‘progressive’ and in line with the idea that the natural resources are much more valuable in ‘poor Alaska’—as some of us have come to term it—than in the United States proper.

H. W. MACFARREN.

Williston, North Dakota, June 29.

ALASKA miners have had much to contend with in their efforts to discover ore, but the first comers have developed great ingenuity in monopolizing a creek, once a discovery is made. There being no limit to the number of claims that can be staked, and power of attorney being recognized, only the amount of wood available and the length of the telephone directory at hand has determined the territory covered by ‘association claims.’ At Aniak they have gone even further. The men first on the ground covered the creeks with claims. These they promptly leased to themselves. The newcomer, therefore, who wants a ‘lay’ must content himself with a sub-lease. Such a system must operate to limit development except where the discovery is so obviously rich as to lead men to take even unfair chances in the effort to develop a mine.

### NEW YORK

NEWS FROM THE COPPER MINES.—A LARGE COMMISSION.—  
TONOPAH.—MARKET RUMORS.

The directors of the Tennessee Copper Co. have declared a dividend of \$1 per share. The last dividend was paid in February and was at the rate of \$1.50 per share. The directors failed to state the period which the present disbursement covers, and the annual rate is consequently left in doubt. The stockholders of the Ohio Copper Co. have voted in favor of the reorganization plan under which the holders of the old stock are permitted to exchange their present holdings on the basis of share for share of new stock upon the payment of \$1 for each share of old stock held. The new stock is issued as having \$3 paid on a par value of \$5. This will give the company a call of \$2 per share upon the stock, and amounts to an ability to assess without going through a reorganization. The \$2,000,000 mortgage given to secure the bond of the La France Copper Co., covering the Lexington mine, the Basin reduction plant, and several mining claims at Butte, is being foreclosed by the Lincoln Trust Co. The suit for a receiver to take charge of the Stewart Mining Co. is soon to be heard in Boston. Besides asking for a receiver, the plaintiffs are demanding that a large amount of treasury stock be returned to the company as having been wrongly issued to F. A. Heinze and his associates, and also demand an accounting from each of the defendants.

There is a well defined rumor that the Utah Consolidated is to cease operations. Should it do so, it is probable that the plant of the International Smelting & Refining Co. at Tooele, Utah, will become exclusively a customs smelting plant. There is hardly a property in the country that has gone through all stages of mining activity any more completely than Utah Con. Originally opened as a gold mine—and a very real one—it later developed into what was then the world's lowest-cost copper producer. The recent addition of lead stacks to the plant at Tooele was made for the purpose of taking care of the lead ores that were being developed in Utah. The shares of the First National Copper Co., which controls the old Balaklala, and which was at one time one of Lawson's market features, have been exceedingly weak in the New York market on the strength of a report that a large part of its fuel and mine supplies has been sold to the Mammoth Copper Co. N. L. Amster, of Boston, has started shipments from his R. R. R. property near Patagonia, Arizona, to the Copper Queen smelter, and is sending out one carload per day of 10% ore.

L. D. Ricketts, of the Greene-Cananea, and W. D. Thornton, also a part of the Cole-Ryan forces, are both at the Inspiration property on a tour of inspection. Inspiration is looked upon as a possible factor in some coming consolidations, and it is believed that the controlling interests are not endeavoring to bring it to the point of production in record time until some additional properties shall have been secured.

Recently the workmen employed by Henry C. Frick began tearing down the old Lenox Library in Fifth avenue, New York, which was erected in 1865. The copper roof was found to be as good as when it was placed on the building. When the roof was purchased, copper was selling as high as 50c. per pound, and the cost of the copper sheets was considerably in excess of that figure.

The amount of interest that prevails in the Cobalt issues is evidenced by an inquiry made by one broker of another for a market in Nipissing; the quotation was given \$7.62 to \$7.87, 100 shares sold during the entire week. The company is in a strong financial position and has over \$1,000,000 of cash reserve. Nipissing is now doing some of its exploratory work with a hydraulic giant. David Fasken, one of the leading members of the legal profession in Canada, has brought suit against the McMartin-Timmins-Dunlap syndicate for a commission of \$640,000

which he claims he earned in the sale of the La Rose to E. P. Earle, William B. Thompson (of Thompson, Towle & Co., of New York), and their associates. The contention of the defendants is that Mr. Fasken's services were only those of an attorney and that he was not acting as selling agent for the property.

Tonopah issues have been a feature of the New York mining market. The fire which destroyed a part of the business section of the camp gave the bears an opportunity for a little action, but when it was learned that no mining property was destroyed the market quickly regained all lost ground. Traders in Butte & Superior were somewhat stampeded at a story that litigation on the company had been started by W. A. Clark, who owns the adjoining Elm Orlu property. Mr. Clark was one of the original owners of Butte & Superior, and it is not believed that any question will arise that cannot be settled without resort to the courts. D. C. Jackling is now making an inspection of the Butte & Superior and is to go from Butte to Alaska in behalf of the Guggenheim interests there. The Isle Royale and the Lake Copper Co. interests, headed by Reginald C. Pryor of Houghton, Michigan, have organized the Onondaga Copper Co., holding some 10,000 acres of ground adjoining the White Pine property.

### BOSTON

BRADLEY PROCESS AT BUTTE.—UTAH COPPER PUZZLING.—  
BIDDING FOR THE BLUESTONE.

Boston is waiting and watching for the real news from the Copper Extraction Co.'s experiments at Anaconda on the slime of the Anaconda company. The Copper Extraction Co. is the name of the company operating the Bradley process, which is owned by the inventor, Mr. Bradley, and A. C. Burrage and Thomas W. Lawson, of this city. Mr. Burrage financed the building of the experimental plant at Anaconda, and has a representative at Anaconda watching the experiments. The plant has been shut down from time to time to make repairs and readjustments, so it has been hard and slow work finding out what is going on. It will be remembered that the Bradley process is the one which Lawson brought out with a great flourish of trumpets three or four years ago to begin treatment at the Santa Rita (now the Chino) mine. He afterward stated that the Heinze interests in Ohio Copper were securing from him the rights to use the process in treating its low-grade ore. He exploited the new process extensively in newspaper stories and then it dropped out of sight until it came to light again in connection with the experiments with the Anaconda slime. The plant which Mr. Burrage has built at Anaconda has a capacity of 250 tons per day. The Anaconda company has over 1,000,000 tons of slime piled up at the Washoe smelter carrying about 2½% copper and about \$1 per ton in gold and silver. This is promising material for copper extraction when it is recalled that it is about the average of the recovery of the large mines in Nevada, Utah, Arizona, and New Mexico.

There are two opinions in Boston regarding Utah Consolidated. The *News Bureau* faction is bearish upon the issue, while G. L. Walker of the *Boston Commercial* claims to have "information from authentic sources that Utah Consolidated will have a very profitable year." Mr. Walker may be considered somewhat in the line of a specialist on Utah Consolidated, since he led the insurgent fight, two years ago, to take the management away from Urban H. Broughton. The *News Bureau* printed a story that underground developments at the Utah Consolidated continue to be disappointing and that there were rumors in the West of the mine being shut down. The *Boston Commercial* telegraphed R. H. Channing, Jr., at Salt Lake City, and received a denial of the story, which is published. Utah Consolidated has been, in the language of the Street, a 'bad actor,' and market interests here are prepared to hear and believe the worst about it. It has been going from bad to worse so long that traders associate the name

of this one-time show property of Bingham with slow but sure disaster.

"Bluestone, Bluestone! Who's got the Bluestone?" A variation of the old nursery game is going on in the bidding for J. R. De Lamar's copper mine, the Bluestone, at Yerington, Nevada. It has been published in the East more than once that this property is to be taken over by the Mason Valley. It is said that the Gunn-Thompson interests have agreed to pay Mr. De Lamar \$1,500,000 for the property. I met the representative of one of the large interests of the Yerington district here a few days ago, and he told me in confidence a story quite to the contrary. He says the ownership of the Bluestone is to pass in that district, but not to the Mason Valley. The Bluestone, while inactive, has been one of the notable copper prospects in the West for the past six years. The bluestone from this mine was shipped 60 years ago to the Comstock, 35 miles away, to be used in milling the silver ores there. Mr. De Lamar has spent approximately \$350,000 in developing the Bluestone mine. It has been opened to a depth of 540 ft., and drilling operations have been conducted to a depth of 750 ft., proving that the ores go that deep. The Bluestone claims developed ore amounting to 1,600,000 tons, averaging 2.6% copper. Magnetic separation tests have demonstrated that a saving of over 98% of the copper can be obtained, yielding a self-fluxing produce which averages over 15½% copper. The Bluestone is an interesting mine, and Boston would like to see it acquired and amalgamated by one or the other of the dominant interests in Yerington, so that it would no longer be inactive. I believe there will be a spirited contest to secure control of this property, and it is by no means settled that the Mason Valley interests will get it.

## LONDON

PODEROSA MINE UNPROFITABLE.—UNFAVORABLE WORKING CONDITIONS.—MINERAL OUTPUT OF FEDERATED MALAY STATES.

The Poderosa copper mine has been one of the unsuccessful English speculations in South America. A company was formed in 1908 to acquire the mines from local owners, situated in the Collahuasi district of Chile, not far from the Bolivian border. The management of the properties was placed in the hands of Robert Hawxhurst, of San Francisco, who was subsequently succeeded by C. H. MacNutt. Results have been disappointing, owing to the many difficulties of working and to the unsatisfactory nature of the orebodies. The altitude, 15,000 ft., the climate, the cost of transport, and scarcity of supplies, all have combined to hinder energetic operations. The flooding of the mine in March 1911 seriously interfered with work, and the provision of additional pumps was a tedious affair. In addition, the last wet season and the winter were both unusually severe and long, and their effects on the health of the men and on the condition of the mine were disastrous. Not only did the production fall, but the cost was increased. The amount of ore exposed recently has been disappointing, and a large proportion of the output during 1911 came from the auxiliary veins which at best are narrow and irregular. During the year 18,357 long tons of ore was raised, of which 15,577 tons came from the Poderosa and the remainder from the San Carlos and Rosario mines. The average assay was 17.3% copper. In addition, 27,776 tons averaging 3% copper was raised and placed on the dump for future concentration. The shipments were 13,392 tons averaging 22% copper and 7½ oz. silver; this was sent by rail to the port of Mejillones, whence it was forwarded partly to America and partly to Europe. The ore reserve on December 31 was calculated by Mr. MacNutt at 21,000 tons averaging 22% copper, mostly at the Poderosa and San Carlos. In addition, there is 110,000 tons on the dump averaging 4½% copper. The net proceeds from the sale of ore was £112,707. The mining expense was £105,947, and £19,649 was allowed

for depreciation. The loss for the year was £16,995, which brings the debit balance to £47,033. The financial outlook is therefore decidedly discouraging.

The output of the Federated Malay States mines in 1911 is summarized in the report of the Warden of Mines, recently made public. The total tin output of the year, 44,149 tons, was reported earlier, and the additional statements furnished by the Warden are somewhat lacking in detail, as is but natural, since the tin industry is so largely in the hands of the Chinese, who are not anxious to furnish accurate figures. Of the 196,500 men employed in mining, 189,000 are Chinese, 4600 Indians, and 2500 Malays. The year's output in piculs<sup>1</sup> of some of the larger companies is as follows: Tronoh, 64,780; Pahang Con., 18,181; Serendah, 9070; Kampar, 8645; Tambun, 8092; Lahat, 7403; Kalumpang, 5447; Batang Kali, 4959; Chenderiang, 4306; Roman Tin (vein), 4069; Menglembu Lode Syndicate (vein), 3833; Société des Elains de Kruta, 2344; Sun Wen, 2705. The North Tambun and Khan Kellas companies have installed Australian dredges, but did not start in 1911. Several French and German companies are in process of development. The production of tungsten was 2816 piculs, valued at £84,500 (local currency). The gold output was 9228 ounces, a large decrease, owing to the decreased output at Raub, only 8581 ounces.

## PIOCHE, NEVADA

RAILWAY OPEN.—SHIPMENTS RESUMED.

The railroad spur, 8½ miles long, recently built by the Prince Consolidated Mining Co. from Pioche station to the Prince mine, was opened on June 30. A special excursion came from Salt Lake City to take part in the cere-

PRINCE CON. SHAFT, PIOCHE.

mony of driving the golden spike, with appropriate speech-making. In this excursion were represented a majority of the business interests of Salt Lake City, especially the banks, smelters, attorneys, brokers, and many commercial houses. On the train that went out to Caliente, carrying the excursionists Monday afternoon, were 23 cars of ore furnished by the Prince Consolidated, 12 cars from the Prince and 11 from the tailing dump at Bullionville.

The control and management of the Prince Consolidated still remains with the Godbe brothers, but an option on the control of the stock has been given to a syndicate including Charles E. Knox of Tonopah, John Kirby of Salt Lake City, George Wingfield of Reno, and others. A payment of \$20,000 has been made on this option, which will undoubtedly soon be exercised and the management pass to the new owners. Nearly forty years ago W. S. Godbe came to Pioche, saw what the camp had done, and determined to have his part in the riches which he foresaw must

<sup>1</sup>The picul = 133 pounds.

still be here. He first purchased the tailing dump at Bullionville, and began the campaign which has now reached fruition. At present about 300 tons per day is being shipped from the Prince, and an average of perhaps 400 tons from the tailing beds at Bullionville. It is the expectation of the management to continue shipments from the tailing beds for a year, and to increase the Prince shipments soon to 500 tons per day. The Nevada Utah Mines & Smelters Corporation is beginning to straighten out its tangles. A number of the most embarrassing obligations have already been settled in cash. From these indications it is generally believed that Allen H. Rogers, engineer for the Nevada Utah, who recently made careful examination of the properties here, reported favorably.

### KALGOORLIE, WESTERN AUSTRALIA

#### LABOR UNREST.—POOR RESULTS AT THE LANCEFIELD.—APRIL GOLD PRODUCTION.

There is a spirit of unrest among the mine and other employees in this state, as in every country in the world. No sooner was the engineers' dispute settled than the molders went out, though they returned under old conditions after losing eight weeks' pay at £5 to £5 1d. per week, besides overtime. The union called out the only three molders employed on the Lancefield mines, with the result that Bewick, Moreing & Co., who were praying for an excuse to close down the mine, promptly did so, and threw 450 men permanently out of work. The shovelers and trammers on the recently started Yuanmi struck for an advance from 11s. to 11s. 8d. per shift. As only 18 men were affected, the extra 8d. was granted and the men signed a three-years agreement on that basis. All the industrial agreements at the Kalgurli expire on September 30 on a month's notice on either side. The men are already holding informal meetings, and the trammers and shovelers will claim higher wages. The former have the worst job in the mine, as they are the first to return after firing, run the greatest risk of miner's complaint from smoke, fumes, and dust, and also are most commonly exposed to falls of ground. Even if a raise in pay is granted, it is more than probable that nine-tenths of these laborers will desert the mines for work on the transcontinental railway which may start any day. Their places will be filled by Austrians and Italians, who have been immigrating in large numbers, expecting to work on the railway. The present Labor Government intends giving preference to union men, even for clerical work, and this will debar foreigners, who rarely join local unions. The railway will require two or three years to build, and employ hundreds of men, and as many of these will be prospectors, new gold and mineral fields may be found in hitherto inaccessible country.

The Lancefield, after producing £830,000 from 540,000 tons at a loss, has closed down, and it is hard to say when it will be reopened. The vein varies from 25 to 28 ft. in width, and the ore yields over 30s. per ton, but costs have been about one-sixth more; treatment alone costing 17s. 6d. per ton. The mine was originally equipped with a 40-stamp mill, but when the sulphide zone was reached the ore was so impregnated with arsenopyrite that extraction without roasting was found impossible. New capital was raised to the extent of £60,000 and a roasting plant constructed, but the design, although a copy of that on the South Kalgurli, was so faulty and the construction so poor that the roofs of the furnaces collapsed almost at once, and work had to be stopped. More capital was raised and the plant remodeled, but a faulty plant can never be remedied, and an entirely new plant will probably have to be provided at a cost of another £50,000 or £60,000. The vein at 1000 ft. is over 20 ft. wide and assays over 40s., so that there are great possibilities in the mine, if an economical plant is installed.

The Mountain Queen at Southern Cross, one of Bewick, Moreing & Co.'s mines, started crushing with a

2-head Holman pneumatic stamp in January, and the output gradually increased until in April 3735 tons was treated, yielding £3446 at a profit of £1129. The ore is soft and oxidized, and the tailing consists almost entirely of slime carrying nearly as much gold as has been saved. A Cassel's vacuum slime-plant has been ordered, and should more than double the profit. The ore developed above 200 ft. is estimated at 58,500 tons, worth 34s. 6d. by assay. The Queen of the Hills, another Bewick, Moreing & Co. new venture, is developing well. Above the 160-ft. level 70,800 tons assaying 53s. 11d. has been developed, and sinking is in progress. This mine will also be equipped with a Holman pneumatic drill and a suction gas-engine, similar to the Mountain Queen, but there seems to be some difficulty in raising the money at the moment. Bewick, Moreing & Co.'s operations at Porcupine have not been a success, nor their oil ventures at Maikop, in Russia, and at present they are opening an old mine in California, all of which requires capital.

During April the gold mines of Western Australia produced 107,392 ounces fine, and paid £108,219 in dividends. The chief producers were:

### BRITISH COLUMBIA

#### REPORT OF THE MINISTER OF MINES.—PROGRESS IN SLOCAN DISTRICT.—MINING AT AINSWORTH.

The annual report of the Minister of Mines for British Columbia for the calendar year 1911 was issued by the Provincial Department of Mines on July 3. The preliminary review and estimate issued by the department early in the current year showed \$23,211,818 as the estimated value of the 1911 mineral production. The revised returns included in the Annual Report give the value as \$23,499,072, so that the estimate of the provincial mineralogist, published shortly after the close of the year, was only \$287,256 short of the actual total value for the year. The report contains much of interest apart from the statistical information. Several of the gold commissioners of the province give particulars of mineral claims and mining operations in their respective districts, and the provincial mineralogist contributes reports and compilations of data on various districts and some important mines, notably a number in Slocan district, the Britannia mine, the Skeena district (both mineral claims and coal areas), and others. His notes on French's process for the separation of zinc and lead, and on investigations made in connection with the reported discovery of metals of the platinum group in dikes in the vicinity of Nelson, are of particular value, since they will serve as a warning to the public to be

careful before spending money on them until the reliability of statements made in connection with these matters shall have been thoroughly tested. The report gives particulars of the French zinc process, and some results of investigations made, but adds that the department "has made no attempt to test the commercial value of the process, but has made some investigation as to the principles involved." The results of these investigations, it may be added, do not indicate complete success of the process. As to the platinum, samples of the dike and concentrate were supplied by the mining company chiefly interested and vouched for "as being from the dike, and from that part of the dike reported to have given results in platinum metals." Identical samples sent by the department to eminent chemists in London and New York, as well as to the laboratories of the Geological Survey of Canada and the provincial department of mines, were reported on, without exception, as not containing any of the platinum metals. The concluding paragraph in the official account of this investigation runs thus: "As will be seen by the evidence just given in detail, this bureau has tried impartially to ascertain whether there is any foundation of fact in the alleged discovery of the platinum metals in these dikes, but the conclusion which must be arrived at is that they do not exist in the material tested. Should it be claimed that these metals do exist in other dikes in the vicinity, that fact will have to be thoroughly established before it can be accepted."

Mining in the Slocan district of West Kootenai appears to be on a better basis now than at any time for a number of years past. In the vicinity of Slocan lake, at what is known as Fourmile or Silverton, there is much activity in three mines, namely, those of the Standard Silver-Lead Mining Co., Van-Roi Mining Co., and Silverton Mines, Ltd. During six months to July 1 the Standard has shipped to the smelter at Trail about 4800 tons of sorted ore and silver-lead concentrate. Its mine and concentrating mill are being regularly operated. Results are profitable, for in April a dividend of  $1\frac{1}{4}\%$  per share was paid on the company's 2,000,000 \$1 shares, while in May, June, and July dividends, each of  $2\frac{1}{2}\%$  per share, have been paid. The total amount distributed in the four months is \$175,000. It has been announced that it is expected the company will be able to pay a monthly dividend totaling \$50,000 for some time to come. The Van-Roi mine appears on the published list as having shipped 1500 tons of silver-lead concentrate during the first six months of this year. This company also makes a silver-zinc concentrate, but no information has been obtained as to its quantity. Recent reports are to the effect that another orebody has lately been found in the mine. The Silverton Mines, Ltd., has had the misfortune to be deprived of the use of the Wakefield mill, which has been destroyed by fire. The company leased this mill, and it had been engaged in experimental milling for some time, to determine how best to recover the high silver content of its Hewitt-Lorna Doone mine ores, some of which are rich in ruby silver.

The most satisfactory development in the Slocan district of late has been the finding of high-grade ore on the 1400-ft. level of the Rambler-Cariboo mine, in McGuigan basin. Large shoots of ore of excellent grade has been opened on various levels down to the 1200-ft., but similar ore had not heretofore been found on the lowest (1400-ft.) level. Construction of an aerial tramway from the mine down to the new millsite alongside the railway, and equipment of the concentrating mill, are in progress. The branch rail-

way is nearing completion also, and it is expected that in the ensuing autumn shipment of sorted crude ore and silver-lead concentrate will be considerable.

More information concerning mining in Ainsworth division will be given later. Just now the position must be briefly summarized. At Retallack & Co.'s mine (the old Whitewater property) development of orebodies found during the winter is being pushed, in readiness for shipment of ore as soon as the railway shall be available for its transportation. The Utica, also, is awaiting similar facilities for sending its ore to the smelter.

## PORCUPINE

PORCUPINE MILLS AT WORK.—SALE OF THE SCOTTISH ONTARIO.—DEVELOPMENT NOTES.

At latest accounts the four mills at the Porcupine were all being satisfactorily operated, with, of course, occasional interruptions for adjustment of machinery. The management of the Dome continues to pursue its policy of reticence as to the results of milling operations, and the others have so recently got fairly under way that accurate figures as to the output are unavailable. Estimates give the daily

PROSPECTING AT PORCUPINE.

tonnage of ore handled by the mills at 615 tons, and the aggregate value of bullion produced at from \$40,000 to \$50,000 per week. The Dome is shipping bullion at regular intervals and its output is supposed to approximate \$3000 per day. The Hollinger made its first shipment of a brick worth \$5000 on July 6. It is only treating lower-grade ore until the mill is perfected. The Vipond is only working a little more than half capacity and has not so far made a clean-up. It has now 6000 tons of medium-grade ore on the dump, and stoping from the 200-ft. level to the 100-ft. level is in progress. The Jupiter is in good ore at the 100, 200, and 300-ft. levels. On the second level four veins have been found, two of them having visible gold. The Hughes is in full operation again, having completed its new compressor and steam plant. The shaft will now be sunk to the 200-ft. level and cross-cutting and driving undertaken at 150 and 200 ft. A new 6-drill compressor has been ordered for the McEneaney, on which a vein 5 ft. wide at the 300-ft. level is yielding ore worth about \$25 per ton. Negotiations for a sale of the Scottish Ontario to British capitalists are pending; engineers, who examined the property for the prospective buyers, having reported favorably. Peter McLaren, the engineer in charge, has gone to London in connection with the deal. The McIntyre is in rich ore at 300-ft. level in No. 1 and 4 shafts. The Plenaurum has cut a quartz stringer 3 ft. wide, running at right angles to the main vein at the 200-ft. level. Free gold shows in a small streak. The Miller, Middleton, and Dixon-Gillies claims are being rapidly proved. At the former there is a 125-ft. ore-shoot that will average \$6 per ton. At the Dixon-Gillies three veins of high-grade character have been cut at depth.

## General Mining News

### ALASKA

#### CORDOVA

Shortage of labor at the Kennicott mines was reported recently. The new concentrator is running night and day, and shipments have begun. The crude ore is said to assay 25% copper, while the concentrate contains 65% copper and 18 oz. silver. W. H. Seagrave, the manager, has also started men at work on the Jumbo.

#### FAIRBANKS

Additional information regarding the tin ore found near Hot Springs has been made public. Stream tin here attracted attention of Falcon Joslin, three years ago, and at his instigation a Mr. Robinson took up the search, which has now resulted in the discovery of an important tin-bearing lode crossing Sullivan, Tofty, and Idaho gulches. The average width of the lode is 12 ft., and the orebody has been traced by trenching 3700 ft. The dike with which it is associated has been followed 10,000 ft. The average value of the lode has not been determined, but the ore is obviously of workable grade.

Seven stamp-mills are now in operation in this district and freight receipts on the railway have increased 34% over the corresponding month of 1911. Angus McDougall is buying a 2-stamp Nissen mill to be placed on the Pioneer claim. The Newsboy shaft is now 400 ft. deep and the grade of ore continues satisfactory.

#### NOME

The season opened with a rush, June 15, with the *Senator*, *Victoria*, and *Umatilla* in port. The *Edith* and the *Sheridan*, the latter carrying troops, got caught in the ice and were delayed for some days. Twelve new dredges are reported as arrived or on the way, and of these four will be built by the Union Construction Co., one by the Yuba Construction Co., two by J. S. Kimball, two by American Construction Co., and one by the Union Iron Works.

#### SEWARD

(Special Correspondence.)—Conditions in the interior are unusually favorable, the season having opened several weeks earlier than usual. The Gold Bullion Mining Co., which is mining a high-grade gold-quartz vein on Craggy creek, a branch of Willow creek, and 35 miles from Knik, began milling June 1. The plant includes seven stamps and is in charge of W. E. Bartholf.

Seward, June 5.

The Kenai-Alaska G. Co. has ordered from the Tren-ton Iron Works an \$200-ft. tramway which is to be in operation about August 1. The Rotchford dredge of the Kenai Dredging Co. has been started and is reported to be working satisfactorily. Placer work is active on Stetson creek. Harper Bros. are now ready to pipe into the boxes. The ground was prospected last year. The Kenai M. & M. Co. has discarded the Ruble elevator and will also pipe direct into boxes. Hobson & Davis are hydraulicking on Bear creek and have already cleaned up \$3500. Nutter & Dawson have 14 men at work on Cow creek and have been piping for several weeks. Nels Anderson and Nate White have completed a 500-ft. drainage adit on Lynx creek, and Adolph Young, who has been working alone on Gulch creek, while short of water, reports an average of \$11 per day. Mike Connolly and J. A. Z. Turner are busy on Six Mile creek, and John Hirshep, on Palmer creek, is getting ready to mill the rich quartz discovered last fall.

### ARIZONA

#### GILA COUNTY

(Special Correspondence.)—At the McMorris mine in Richmond basin, 8 miles northeast of Globe, the 800-ft., 2-compartment shaft has been retimbered to the 200-ft. level. The McMorris mine was a producer of rich silver

ore in the early days of Globe, when only the highest grade ore could be shipped. The mine is being operated by the White Metal Development Co., of which the principal stockholders are H. B. Snell, R. B. Hegardt, W. D. Fisk, A. W. Crawford, George Wilson, and others. Mr. Wilson is superintendent. Beautiful specimens of wire silver have been taken from the group of claims being worked by the Rice brothers and W. D. Fisk, 8 miles north of Globe. The ore occurs as a 2-ft. vein in diabase, and consists of native silver, hornsilver, and a mixture of copper and silver glance. At the Iron Cap Copper Co. the general manager, F. A. Woodward, has been authorized to proceed with development, and driving will be started west on the 800-ft. level of the Williams shaft.

Globe, July 13.

#### MOHAVE COUNTY

At the Tom Reed mine the clean-up for the month yielded a bar worth \$79,000. The electric hoist is now in operation and the mill capacity is being increased. The Gold Road is producing a \$20,000 bar at each weekly clean-up. The new machinery for the addition to the mill is expected within two months, and the water supply is now sufficient for a 500-ton mill. W. H. Hall is operating the Mocking Bird, in the Weaver district, and has developed a good quality of \$15 to \$80 ore. The mill is expected to be in operation soon.

#### PINAL COUNTY

(Special Correspondence.)—The Lake Superior & Arizona Mining & Smelting Co. has given an option on its property to the American Smelting & Refining Co. The holdings consist of 17 claims adjoining the claims of the Magma Copper Co. at Superior, 30 miles west of Globe. The A. S. & R. Co. is given until October 20 to unwater and examine the mine, after which, should it so elect, it is given two years in which to develop the mine and make the payments. The purchasing company has the choice of making total payments of \$400,000 cash and two-fifths of the authorized capital stock of the company which it shall organize to operate the mine, or, under an alternate plan, of \$800,000 cash if it elects to purchase the property at the end of one year or \$1,000,000 cash at the end of two years. F. W. Hoar, of Globe, represents Lake Superior & Arizona company, and J. Kruttschnitt, Jr., representing the A. S. & R. Co., has gone to Superior to make preparations for unwatering the mine. The property is opened by an inclined shaft 1300 ft. deep and has about four miles of drifts. There is a considerable amount of oxidized ore exposed, averaging about 4% copper, and \$50,000 worth of higher-grade ore was shipped from one stope, but it is upon the possibility of opening up sulphide ores at depth that the future of the mine depends. Sulphides were beginning to appear at the bottom of the shaft when the mine closed down, on account of lack of funds, three years ago.

Florence, July 13.

Negotiations are being made for the sale of the Mammoth mine to the American Vanadium Co. The property was formerly a rich one, but has not been worked for over ten years.

#### SANTA CRUZ COUNTY

M. P. Freeman, of Tucson, has bonded the Black Diamond and Isabel properties, in the Santa Rita mountains, to Fred Challman, of Bisbee. Shipments of good ore carrying lead, silver, and copper are being made to El Paso. James Harrington, of Bisbee, has leased the property of John Allen and Ed. Castañeda, in the Sheedy district, and is shipping ore to El Paso. At the Elephant Head property an air-compressor has been installed, and work on a 1500-ft. adit will be started at once. The Border Mines Co. has found good ore in the Austerlitz property and has a 3-stamp mill at work on \$5 to \$20 ore, and is shipping two to three tons of concentrate, worth \$80 to \$100 per ton, per day to El Paso.

#### YAVAPAI COUNTY

(Special Correspondence.)—The Swansea smelter will

blow in in a few days, after some months of inactivity due to financial difficulties. About five carloads of ore per day will be shipped to Swansea from the Bluebell mine, and an equal amount shipped to the Humboldt smelter from the Swansea mines, as each needs the other's ore for fluxing purposes. The Yuma-Warrior Mining Co. has acquired the old Harqua Hala property and will immediately begin development. A. J. Pickerell reports that the adit on the Tillie-Karibuck group on Slate creek is in 2000 ft. and has cut a number of good ore-shoots. The new machinery on the Commercial Mining Co.'s property in Copper basin is in place and will be ready to run in a few days.

Prescott, July 13.

#### YUMA COUNTY

Work has started at the Horn mines, in the Turtle mountains, southeast of Parker, which were recently taken over by W. A. Clark. J. W. Fink, manager for the D. & W. Mining Co., has recommended to the shareholders that a mill should be built. Five levels have been opened, to a depth of 700 ft., and 3500 ft. of underground work has been done. Rich ore has been found on the Fortuna group and development is in progress. It is reported that Frank Bowers has sold his potash claims, near Blythe Junction, for a large sum.

### CALIFORNIA

#### CALAVERAS COUNTY

(Special Correspondence.)—A new shoot of quartz has been intersected by the prospect winze at the Cross mine. The find was made at an approximate depth of 1000 ft. Ore conditions are stated to be improving at the Gold Cliff. Both these properties are controlled by the Utica Mining Co. A winze has been started at the Angels mine and will probably be sunk to a depth of 200 ft. Fair-grade ore is reported. Development of the shoot recently found on the 900-ft. level of the Lightner is progressing steadily. The orebody is reported widening, with ore of milling grade. It is understood that the shaft will be sunk to a depth of 2000 ft. before systematic stoping is commenced. The starting of the mill at the Smyth has been delayed by the burning out of a transformer. Free gold and sulphides are showing as the wide vein is opened. The North Star management is driving drifts to prospect the southern portion of the property. Unwatering of the Reiner gravel mine is progressing, and it is expected to clear the workings within ten days. Sinking will be resumed and drifts extended to the centre of the channel.

San Francisco people are interested. Placer mining in the vicinity of San Andreas is active. Work has recently been resumed at the Reed, Chapman, and Cassinelli properties, and plans are under way for reopening the Lloyd. A new shaft is being sunk at the Reed, and good gravel is said to be showing in the Chapman workings. It is rumored the Penn Mining Co. may experiment with a new process for smelter-smoke control at Campo Seco in addition to continuing tests with the Thiogen process. The Calaveras Copper Co. is increasing the force of miners at its Copperopolis mines, and it is expected the smelter will be blown in before the end of August. The company reports a large tonnage of excellent grade ore developed. The deposits have been proved to a depth exceeding 600 feet. Angels Camp, July 13.

#### MODOC COUNTY

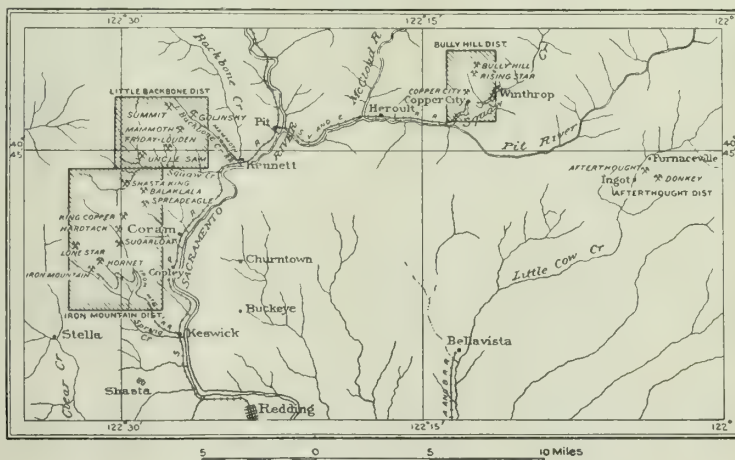

(Special Correspondence.)—A 2-ft. ore-shoot, assaying \$18 to \$125 per ton, is reported showing in the surface workings of the Gold Shore. The work is in charge of Fred Bell, formerly with the Goldfield Jumbo Mining Co. The Ft. Bidwell Con. Mines Co. has overhauled its 10-stamp mill and made arrangements for Pierce amalgamators and Wilfley concentrators. It is understood that a

cyanide plant is also planned. Sampling of the old workings is progressing, and plans include the sinking of the shaft to a vertical depth of 400 ft. About 30 miners will be employed before the end of July, according to present plans. This company has developed a fair reserve of milling ore in the Mountain View and Sugar Pine claims and controls an extensive acreage. Detroit and Los Angeles people are interested. It is stated that \$50,000 is available for preliminary operations. Four sets of lessees are preparing to start work on the Big Four. Several surface discoveries of promise have been made. Fitful falls of snow have somewhat interfered with work in the district, particularly on the northern slopes.

Ft. Bidwell, July 12.

#### SHASTA COUNTY

The Afterthought Copper Co. has purchased the Anderson-Bella Vista railroad from the Terry Lumber Co. and is now completing a survey for the extension of the road to its smelter at Ingot. The new railroad company will be known as the California, Shasta & Eastern Railway Co., and location surveys are completed for the first six miles above Bella Vista. The surveyors are now making the necessary corrections and completing their surveys for the upper six miles preparatory to accepting bids. At the mine the company has only a small force of men at work keeping the mine in repair and doing a small amount of development work. The construction of the road and a suitable reduction plant for the recovery of zinc, copper, gold, and silver are most important at present, as there is enough ore already developed to last for several years with a 300 or 400-ton daily capacity. At the smelter three or

PART OF SHASTA COUNTY.

four men are at work developing a process for the recovery of metals. This has been developed beyond any doubt as to the advisability of adapting it to the treatment of the ores. As only two or three patents have been secured on this process, and several more are planned, it is kept private for the present. The company expects to install a 25 or 50-ton unit, in the near future, having tested the process out on only a 100-lb. capacity basis.

#### SIERRA COUNTY

(Special Correspondence.)—W. M. Beggs and associates of San Jose have let a contract to the Union Iron Works for the immediate erection of a 5-stamp mill at the Kate Hardy mine, on Oregon creek. It is planned to commence crushing early in September. A concentrator and cyanide plant will also be installed, and electricity will be employed for motive power. Considerable development in the shape of adits and drifts has opened a good reserve of ore, according to statements of officials. The property lies in the Forest district. It is stated the Bank Mining & Promotion Co. has decided on the erection of a 5-stamp milling plant at the Red Ledge mine, also near Forest. The head offices of the corporation are at Buffalo. Considerable stock is held by Vancouver, British Columbia, people.

W. J. Moulton is superintendent. The mill at the Cleveland, near Downieville, is being overhauled and arrangements made for production. The property is held under bond by Nevada people. Activities have recommenced at the City of Six quartz property, which is under bond to J. W. Henderson of Fresno. The Hewitt brothers have started a 5-stamp mill on their property near Gibsonville. The vein is reported about 20 ft. wide, with streaks of good milling quartz opened.

Forest, July 13.

## COLORADO

### CLEAR CREEK COUNTY

(Special Correspondence.)—A streak of ore 5 in. wide has been uncovered on the La Plata vein on Democrat mountain that mills 281 oz. silver and 16% lead. Shipments have been started. Joseph Broad is the owner. The American Mines Syndicate, operating on Columbia mountain, is moving the Sigafos boring machine from the Georgetown adit to its own property. It is stated that the Kelly adit mill will be brought into commission during the next two weeks. The machinery is being repaired and placed in condition to effect a higher saving than formerly. Ore will be treated from the New Boston mine on Democrat mountain. An average of 16 tons is being shipped daily from the Santiago mine in the East Argentine district. D. H. Burlingame is manager.

Georgetown, July 9.

### JEFFERSON COUNTY

At the Colorado School of Mines a new 14-ft. Littrow spectrograph has been purchased, at a cost of \$1500, through the Vinson Walsh research fund. This fund was given by the late Thomas F. Walsh for the determination and study of rare metals in ores. Because of its sensitiveness the spectrograph has been used to detect adulterations and many cases of poisoning. It has been used to a limited extent to study the flames from steel and copper converters as a means of gauging the different stages in the process. There is still a large opportunity for investigation in this direction. Through the Vinson Walsh research fund this department has already been equipped with all the necessary apparatus to determine radioactive metals. With the new specially constructed spectrograph the school is in a position to cover fully the entire rare metal field.

### LAKE COUNTY (LEADVILLE)

The tonnage produced at Leadville during June was about the same as preceding months, 60,000 tons. There was a slight decline in production by lessees on account of surface water. This trouble has now abated, and the output should be larger during July. The dead-work at the Chrysolite, Fryer hill, is nearly completed, so that shipments of ore, which averages better than 30%, will be increased. Lessees on the south end of the Discovery are down to the 300-ft. level and have opened a pocket of high-grade 'lead sand.' Lessees in the Ella Beelar adit have found a good vein, 1800 ft. from the portal, which assays \$40 to \$50 per ton. The Anderson adit, on Prospect mountain, is now in over 500 ft. W. B. Anderson is manager.

### SAN JUAN COUNTY

The blacksmith shop of the Silver Lake caught fire recently, and before the fire could be extinguished the mine terminal of the tramway was destroyed, with a loss estimated at from \$30,000 to \$40,000. Shipments of ore during June were as follows: Sunnyside, 600 tons; Iowa-Tiger, 175; Silver Lake, 825; Gold Tunnel, 175; Golden Eagle, 25; Pride of West, 25; Bonner, 25; S. E. & M. Co., 25; Gold King, 1250; a total of 3125 tons.

## IDAHO

### BLAINE COUNTY

The Independence M. Co. has obtained an injunction against the Wenatchee M. Co. to restrain the latter from interfering with the operation of the Independence mine and mill. At the Climax five men are now at work.

## IDAHO COUNTY

The clean-up at the Golden Scale placer has been completed, 32,000 cubic yards of gravel having been moved. A race has been cut to the old channel, which was found to be higher on the hillside than was expected. Where found it is 30 ft. deep and the gravel all shows colors. The company is now in shape to begin operation next spring without any dead work being necessary. Work on the 7-mile ditch, to take water from the East fork of the American river, is well under way.

### SHOSHONE COUNTY

Earnings of the Federal M. & S. Co. for the first 9 months of the fiscal year are \$633,700. Dividends are now being paid at the rate of 6%. The company is producing about 4000 tons of lead per month. The Tamarack & Custer Consolidated M. Co. has been formed to take over the Tamarack & Chesapeake and the Custer mining companies. The capital is \$2,000,000 and 25,000 shares will be placed on the market. Both properties will be worked through the Tamarack adit. The lower adit at the Lucky Calumet has cut the vein and it is reported that the management will at once proceed with the construction of a 100-ton mill, to be later increased to 500 tons by 100-ton additions. The Bullion M. Co. expects to start shipping soon. J. H. Taylor is manager. The Alice mine has shut down. Work has been resumed at the Surprise. Otto Nordquist is superintendent.

## MONTANA

### MADISON COUNTY

The Copperville group of quartz claims on Peterson creek have been sold by E. C. Hosmer for \$50,000 to H. A. Bowman, who represents Butte interests. The ore assays 8 to 17% copper and as high as 800 oz. silver per ton. A mill will probably be erected as soon as sufficient ore has been blocked out. A road is being constructed from the railway 8 miles up Ramshorn gulch to the Bedford mine. The Walters Tunnel Co., which is developing the Bedford, will build ore-bins at the railway and a saw-mill at the mine. Large quantities of lead-silver ore are said to be blocked out in the property. W. Walker and M. Johnson are working the Betsy Baker and Gold Coin and have developed large amounts of gold ore of milling grade.

### SILVERBOW COUNTY

(Special Correspondence.)—An option on the Macarona, Montgomery, Altona, the Colleen Bawn, the Amazon, and the Park City claims, situated southeast of the city, has been given to A. B. Wolvin, president of the Butte & Superior company, for the sum of \$170,000. The claims belong to what is known as the Brundy estate, and in order that the agreement might be made, permission had to be secured from the District Court. With the delivery of the option agreement, Mr. Wolvin paid \$1000, and is to pay \$4000 in ninety days, \$5000 in six months, \$75,000 in one year, and the balance, \$90,000, in eighteen months. The Brundy properties have undergone some development work, but have never shown any rich ore, so far as can be ascertained. Some years ago, when the claims were under option to New York capitalists, J. Parke Channing spent considerable time making an examination of the property, but what his opinion of the claims was, never could be ascertained. However, some time afterward the New York capitalists withdrew from operating the property and the option went by default, it having been stated that a controversy arose which could not be adjusted. It is understood that the Guggenheim interests are back of Mr. Wolvin in the matter of this option, but this is only surmised.

Butte, July 13.

It is reported that the Tuolumne will not declare any dividend in August. The company is shipping 200 tons per day, chiefly from the 1600 and 1800-ft. levels. The Snowball vein in the North Butte has been found to be

richer on the 2400-ft. level than on the 2200, the vein being 7 ft. wide and carrying 10% copper.

## NEVADA

### LYON COUNTY

The Mason Valley smelter made a record run on July 6, smelting 817 tons in 24 hours, in its 400-ton furnace. The ore received at the smelter during the week ended July 4 was as follows: From the Nevada-Douglas Copper Co.'s mine at Ludwig, 2580 tons; from the Mason Valley Mines Co.'s mine at Mason, 2249 tons; from miscellaneous mines, 734 tons. Shipments of copper matte from Thompson for the same period amounted to 10 carloads. The Yerington Copper has resumed shipments. A new compressor is to be installed soon. The drift on the Malachite has almost reached the orebody. A 2-compartment shaft is being sunk on the McConnell property and has reached a depth of 30 ft. in ore averaging 6% copper. The Yerington Mountain Copper Co. will begin ore shipment in the near future.

### NYE COUNTY

The new main shaft at the Tonopah Extension has reached a depth of 350 ft. The east drift from the 501 stope has a full face of \$30 ore and development work elsewhere in the mine has added greatly to the known ore reserve. At the

TONOPAH, NEVADA.

Montana Tonopah 888 tons of ore was milled last week, with a 94% recovery. The clean-up for June yielded 3901½ lb. of bullion, valued at \$45,840 and 34.7 tons of concentrate from 4645 tons of ore. The clean-up at the MacNamara for the 15 days preceding July 9, yielded 886 lb. of bullion, valued at \$10,450. The mill is now treating 67 tons per day. The Golden Anchor shaft of the Tonopah merger has reached a depth of 985 ft., and a station is being cut from a drift which will be driven to the vein.

### WHITE PINE COUNTY

The coroner's jury has returned a verdict of death by accidental explosion in the case of the ten men killed by the explosion of the three boxes of 40% dynamite at the Copper Flat pit of the Nevada Con. on July 7. The men were loading a hole in the ordinary way when the powder on the surface exploded, and all were instantly killed. The powder in the hole, and in a nearby one which had already been loaded did not explode. No reason can be assigned for the explosion. High-grade ore has been found on the Morris No. 1 claim of the Giroux Con. Ore from the Taylor dump is being shipped to the smelter. Development is progressing at the Coppermines Co., and arrangements are being made for the installation of a gasoline hoist. Good results are reported from the drilling on the 1245-ft. level of the Boston Ely. Recent development work shows the Emma vein to be 72 ft. wide. The adit of the Smokey Development Co. is in 100 ft., and has a like distance to go before reaching the orebodies disclosed by drilling. The Lead King has several carloads of ore ready to ship, which is reported to contain 80% lead.

## NEW MEXICO

### GRANT COUNTY

The Silver King mine, in the Central mining district, has been leased to J. T. Jones and B. P. Keel. The vein is

reported to be 5 ft. wide at a depth of 25 ft. and to assay \$6.10 gold, 2 oz. silver, and 30% lead.

## OREGON

### JOSEPHINE COUNTY

It is reported that the funds have been secured for the construction of a railroad from Grants Pass 52 miles up the Applegate river to the mines of the Blue Ledge district. E. M. Chester is the representative of the interests concerned. The Soule mine has been purchased by J. D. Densmore, H. McBride, and D. G. Dreger, of Salem. Arrangements are being made for the reopening of the property, which has not been worked in five years. The mining men of the district have sent 3½ tons of ore samples to the Mining Congress, held at Yreka this week. L. E. Crouch has begun suit for \$100,000 damages against several Ohio people for alleged misrepresentation as to the solvency of the Alameda M. Co. The court has discharged the receiver, R. S. Tucker, who was recently appointed. The Alton mine, near Wolf Creek, has let a contract for a 100-ft. extension of the present adit.

## UTAH

The following Utah companies have declared dividends during the first six months of the year:

Bingham-New Haven .....	\$ 45,724
Cliff .....	30,000
Colorado .....	60,000
Daly-Judge .....	45,000
Daly West .....	135,000
Iron Blossom .....	170,000
Opohongo .....	17,978
United States common .....	351,010
United States preferred .....	850,576
Utah Consolidated .....	150,000
Utah Copper .....	3,750,000
Total .....	\$5,605,288

### SUMMIT COUNTY

The Ontario mill is well advanced, and it is hoped to have the reconstructed mill in operation. The mine is ready for the increased output, and the old stope fillings are already being hoisted to the surface. At the New York Bonanza two shipments of ore have been made, and a third is ready; a total of 90 tons, which yields a net return of \$10 to \$12 per ton. M. J. McGill is manager. In the Ontario adit three shifts are at work cutting a station on the 2100-ft. level of the Daly West, and as soon as it is completed stoping will begin. Shipments have been as follows: Silver King, 593 tons; Daly-Judge, 451; Daly West, 198; Sam Hair, 9 tons.

## CANADA

### BRITISH COLUMBIA

It is stated that a new company will be formed to take over the Red Cliff Mining Co. and to acquire a controlling interest in the Tyee Copper Co. It is reported that M. K. Rodgers is negotiating for the Big Missouri group of 16 claims, owned by Dan Lindeberg. The Granby Con. has bonded the Doyle group, on Observation Inlet, for the alleged sum of \$100,000. During the summer \$20,000 will be spent on development. Work has begun on the 2000-ton smelting plant. Shipments of blister copper from the Granby for the first week of July amounted to 435,000 lb. N. McLeod Curran, who recently purchased the Northern Terminus, is developing the property. Rich gold ore has been found 18 miles from Stewart on ground belonging to Dan Lindeberg. The Nickel Plate has two diamond-drills at work and extensive development is being carried on.

The fourth dividend of the Standard Silver-Lead M. Co. in the Slovan district has been declared and amounts to \$50,000. The total to date, according to the *Spokesman-Review*, is \$175,000, giving the property the best record of any mine in the Northwest. The mine has been in operation twenty months and has expended \$150,000 for machinery.

## ONTARIO

(Special Correspondence.)—At the Nipissing hydraulic operations have exposed an extension of vein No. 92, carrying from 1 to 2 in. of high-grade ore, and two other veins. The output of ore for June was valued at approximately \$225,162. The high-grade mill during that month treated 181 tons of ore and the bullion shipments were 326,278 oz. of a value of \$198,824. The principal ore production was from vein No. 73. A 1-in. stringer has been found running at right angles to this vein on the second level, which assays 1500 oz. per ton. At the Provincial a deep bed of conglomerate has been found underlying the slate at the 350-ft. level. So far the best veins of this mine have been found to occur in the conglomerate, and the shaft will be sunk farther in the hope of finding other deposits. The Crown Reserve has declared its regular quarterly dividend of 2% and a monthly bonus of 3%, making total returns to shareholders of 250% of the capitalization. The Dominion Reduction Co. has been organized, with D. N. Steindler as president and Eugene Steindler as secretary-treasurer, to take over and operate the Nova Scotia mill, which is being altered so as to secure increased concentration for the treatment of the conglomerate ores. The Gould Consolidated, which holds a lease of 120 acres from the Peterson Lake, has made an agreement with the Porcupine Syndicate, Ltd., under which the latter will operate the mine. The Porcupine Syndicate will continue development at the 100-ft. level, where several veins have been found which are apparently extensions of Nipissing deposits, and will sink to a lower level. The Cobalt Majestic Co., which is in liquidation, is paying its creditors in full, and the shareholders may also receive a dividend, as some of its claims are likely to bring good prices. Good progress is being made in the construction of the Elk Lake branch of the Temiskaming & Northern Ontario railway on which 400 men are working. Eleven miles of grading has been completed and the rails will be laid as soon as the steel can be secured. The line is expected to be completed by the end of the year.

Cobalt, July 10.

## MEXICO

## SONORA

(Special Correspondence.)—The Tigre Mining Co., S. A., reports the returns for June as follows:

Estimated realizable value of:

Bullion produced .....\$64,877  
Concentrate produced (244 tons).... 57,932  
Shipping ore produced (110 tons).... 27,010

Sundry profits ..... 3,517  
\$153,336

Less:

Mining, including development.....\$20,469  
Milling ..... 33,468  
General expense ..... 3,139  
Marketing ..... 28,517

85,593  
\$ 67,743

Kansas City expenses, including interest on bonds ..... 3,146

Estimated profit ..... \$ 64,597

The mills crushed 5676 tons of dry ore during the month, and the cyanide plant treated 5439 tons of tailing from the two mills, and 2081 tons from the old tailing dumps, an average of slightly over 250 tons per day. A total of 267 ft. of development work was done during the month. To obtain the exact amount realized during the month, complete smelter and refinery returns would have to be obtained, involving a delay of two months. Experience in the past has been that the returns from the mine are within 1% of the final returns.

Yzabal, July 5.

## James Lewis &amp; Son's Copper Report

A further advance in the price of standard copper of £3 per ton has taken place during the first half of June—from £76 2s. 6d. to £79 2s. 6d. for cash. Up to £79 2s. 6d. was paid on June 6, from which there was a recession to £77 15s. 0d. on June 14, due to extensive liquidation to secure profits. This fall was recovered June 17, the closing prices being £79 2s. 6d. cash and £79 15s. 0d. three months. Sales amounted to about 40,000 tons. The statistical position continues very strong, and consumers are threatened with a serious scarcity of refined copper, aggravated by a continuance of the strikes at two of the largest American refining works and the rapid diminution of the stocks held on this side of the Atlantic as well as of those held by American refiners. Electrolytic copper has been sold freely up to £80 15s. 0d. per ton c.i.f., and from warehouse here, American producers being fully sold for delivery up to September.

Statistics show an increased import into Europe from the United States of 21,702 tons, but from other countries a decrease of 13,448 tons. The consumption of Europe is 19,080 tons larger than during the same period last year, but the exports have fallen off 5387 tons. The fact that the consumption of England is 7482 tons less shows the reduced stocks held by English manufacturers, in view of the general admission that both the copper and steel trades have been and are exceptionally active this year. American consumption has increased 23,504 tons. The reduction in European and American stocks for the five months of this year has been 34,654 tons, and on June 1 they were 89,454 tons less than at the same date last year.

Stocks have decreased 955 tons, and the visible supply 2505 tons during the first two weeks of June.

Imports to June 17 were 4429 tons and deliveries 3506 tons less than last year. These latter included 4000 tons shipped to the United States, as against 7900 tons last year. The arrivals in England and France for the first half of June were 11,976 tons, and the deliveries 12,385 tons. The arrivals at Liverpool and in Swansea from the United States were 1427 tons of bars, 300 tons of plates, and 20 tons of matte, equal to about 1725 tons fine; in London 200 and in France 4350 tons fine. The arrivals of Chile in Liverpool and Swansea were 1258 tons and the deliveries 1057 tons, and from other countries 3195 and 3259 tons fine, respectively.

The Chile charters for the first half of June were advised as 2900 tons, including 1925 tons to the United States.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

T. T. READ is in Nevada.

J. A. BURGESS was here Monday.

C. W. MORSE was in San Francisco.

F. J. SIEBERT is on his way to Alaska.

JAMES G. BERRYHILL was in San Francisco.

C. C. BROADWATER has gone to Grass Valley.

W. H. STORMS has gone to northern California.

SUMNER S. SMITH now has his headquarters at Nome.

CHARLES JANIN is expected from Nome early in August.

M. L. REQUA was orator of the day at Juneau on the Fourth.

ALEXANDER P. ROGERS is in California on professional business.

J. M. BOUTWELL passed through San Francisco during the week.

NEWTON CLEAVELAND is leaving for Dawson and Alaska next week.

C. M. DERBY, of the Natomas Consolidated, has gone to Oregon on his vacation.

P. N. MOORE returned to San Francisco from Los Angeles and has gone to Alaska.

GERHARDT ULRICH has left New Zealand for London, where he expects to arrive about September 1.

CHARLES C. SELBIE sailed today on the *Persia* to take a position with the Chosen Mining Co., Yeng Byen, Korea.

E. A. WALL has returned to Salt Lake City from Washington, D. C., where he underwent treatment for his eyes.

GEORGE A. PACKARD has been examining the Nevada-Douglas mine, and was in San Francisco during the week.

E. J. CARLYLE is now in charge of the smelter of the Famatina company, Chilecito, Province La Rioja, Argentina.

G. L. SHELDON expects to sail from Seattle on July 27 for Katalla, expecting to return to Ely, Nevada, within two months.

CECIL BROCK has resigned his position with the Cerro de Pasco M. Co., to take over the management of the Santa Clara group of mines at Morococha, Peru.

Obituary

J. B. CARTER died on July 7 at Moores Flat. Mr. Carter, who was 81 years of age, went to Nevada county in the early days of the gold excitement in California, and remained in the district through its varied ups and downs. For many years he was postmaster at Moores Flat, and his crossing the divide lessens the roll of the pioneers.

SAMUEL UREN recently died at his home in Grass Valley. He was born at Cambourne, Cornwall, in 1851, and in 1873 married Celia Warren, at Swansea, Wales. In 1880 they came to California and settled at Sierra City, where Mr. Uren was employed as a millman for 27 years, moving to Grass Valley in 1907. An expert millman and a good citizen, his loss is much mourned. He leaves a widow, two daughters, and two sons.

R. B. NICKERSON, who died suddenly of heart disease at Livermore, California, Monday, was well known for his work in the Mother Lode and other California regions. He had but recently returned from a year in western Ontario, where he had been in charge of the Mikado mine, in which he and friends were interested. Mr. Nickerson was 49 years old, a genial, likable, and capable mine manager who did his work well and incidentally found time occasionally to contribute to the literature of his profession.

## Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

**ZINC-DUST** used for precipitation of the gold-bearing solution at the Goldfield Con. plant amounts to 0.385 lb. of zinc-dust per ounce of fine gold precipitated. The total cost of precipitation is 7.3c. per ton of ore treated.

**DANAITE** is a cobaltiferous variety of arsenopyrite which contains 4 to 10% of cobalt, thus graduating toward glaucodot (CoFe)AsS. It occurs in the United States at Franconia, New Hampshire, where it is associated with calcopyrite in gneiss.

**BLUE-LINE** prints require so much skill in manipulation that it is not usually practicable for engineers to attempt to make them, as it is very difficult to get the white background clear. Prints with brown lines on a white ground can be made by the use of special papers, and in the larger cities the dealers in drawing supplies will usually make black-line or blue-line prints to order at a moderate price.

**QUICKSILVER** fed into the batteries of the Ready Bullion stamp-mill of the Alaska United amounts to a little more than 1/6 oz. of quicksilver per ton crushed, and small amounts were further used in dressing the plates, on vanners, and in cleaning the amalgam; the total being a little more than 1/5 oz. per ton crushed. This corresponds to 3 1/2 oz. quicksilver per ounce of free gold recovered. The amalgam had an average value of \$5.87 per ounce and yielded a bullion worth \$18.50 per ounce.

**SAMPLES** of gas under pressure from an oil well can be taken by the use of a cloth funnel, made by folding and sewing any strong, closely woven cloth in the form of a cornucopia. The larger end of this funnel should be large enough to encompass the gas pipe from which the sample is to be taken. The smaller end, or apex, of the funnel should be securely tied about one end of a flexible rubber tube one or two feet long and 1/4 to 1/2 in. diameter. If there is a gas-jet at the well, one end of the rubber tube may be attached directly to the jet. The sample is then collected in a bottle in the usual way.

**NICKEL** deposits of China are, through the reorganization of the government and the building of railroads, becoming more of an economic possibility. Nickel is believed to occur in southwestern China in fairly considerable amounts, since the Chinese have from time immemorial smelted mixtures of tin, lead, zinc, copper, and nickel ores, forming natural alloys of variable composition which approximate German silver. The Chinese call this 'pai-t'ung' or white copper, and it is used extensively in the manufacture of candlesticks and other household objects. In spite of its general use, comparatively little is known of the source of the nickel ores, since they occur in southwestern China, where only recently has it been possible to carry on extensive exploration on account of the difficulties of travel and the hostility of the native tribes. Within the last few years railroads have been built through this area and considerable foreign trade is being carried on, but so far apparently no attention has been paid to the nickel deposits. Duclos, the mining engineer who accompanied the Mission Lyonnaise, reported that he found nickel ores occurring associated with copper in a couple of placers in Yunnan and Ssu-chuan. The ores must be comparatively rich, otherwise the Chinese would never have worked them by their native methods, since they ordinarily do not work copper ores which are lower in grade than 15%. Just at present the output is not important, but it is interesting and may have a good deal of economic possibilities.

## Decisions Relating to Mining

Specially reported for the MINING AND SCIENTIFIC PRESS.

### INDEMNITY LANDS—MISTAKE OF SECRETARY OF INTERIOR

A due selection by a railroad company of public lands free from other claims and within the indemnity limits of its grant, vests in the selector a right to the land against all third persons attempting thereafter to initiate a claim to the selected lands under any of the general land laws. When the Secretary of the Interior makes a rejection of an indemnity selection through fraud or mistake of law or fact, if the wrong be not corrected by him of his own initiative by a revocation of the order, then since mandamus will not lie to enforce a reversal of this ruling, the aggrieved party can only await the time when the United States shall have parted the title and then begin his action to have the patentee declared his trustee.

Southern Pacific Railroad Co. v. George L. Arnold, 43 California Decisions, 582. May 28, 1912.

### OIL LEASE—CONSTRUCTION OF TERMS

A lease made by the Osage Indian Nation to an oil company recited that no wells should be drilled upon cultivated inclosures in the Reservation. Subsequent to the execution of the lease, certain Indians inclosed and proceeded to cultivate certain Reservation lands which had not previously been under cultivation. The oil company attempted to sink wells upon such inclosures, claiming that it had a right to do so, the lands being uninclosed and not cultivated at the time the lease was made. It was held, however, that the term 'cultivated inclosure' related to those made after as well as those made before the lease was executed, and that the persons first initiating proceedings to work the uncultivated land would be protected.

Barnsdall Oil Co. v. Leahy et al., (Oklahoma) 195 Federal, 731. April 1, 1912.

### JURISDICTION OF LAND DEPARTMENT IN ALASKA

Certain lode-mining claimants filed an adverse claim in the matter of the Katalla company's application for a soldiers' additional homestead patent to lands in Alaska, asserting as the basis of their claim that the lands in question were, in part at least, mineral in character, conflicted with claimants' lode claims, and were within the limits of a national forest. The Commissioner of the General Land Office held that the Land Department has jurisdiction to determine the mineral or non-mineral character of the land in Alaska, that conflicts between mineral and non-mineral claimants should not be treated as 'adverse claims,' to be decided by courts of law, but are more properly 'protests,' the hearing of which is strictly within the jurisdiction of the Land Department. Accordingly, the Land Department is under no obligation to suspend proceedings pending the final decision of quiet title suits, instituted in this case by both parties, and the mineral claimants were ordered to prosecute their contest against the issuance of patent to the Katalla company under penalty of having the case dropped from the files of the Department. The Secretary of the Interior approved the foregoing ruling, with a modification to the effect that the *prima facie* validity of the Katalla company's application should first be determined before ordering a hearing on the protest.

Low et al. v. Katalla Company, (Land Department) 40 Land Decisions, 534. Jan. 15, 1912.

## Dividends

The Tonopah-Belmont paid a dividend of 25c. per share on July 1.

The United Verde Copper Co. paid a dividend of 75c. per share on July 3: This is the fifth dividend this year.

The La Rose Consolidated has declared a 2 1/2% dividend, payable July 20. This makes a total of 42% dividends paid by this company.

## EDITORIAL

WE have the pleasure of announcing that Mr. M. W. von Bernewitz, recently with the Associated Northern Blocks, and the Associated Gold Mines, Ltd., has joined the San Francisco staff of the *Mining and Scientific Press*. As our Kalgoorlie correspondent and a writer on metallurgical and mining topics, Mr. von Bernewitz is already well known to our readers, and they will, we are sure, be glad to know that his time will hereafter be devoted exclusively to editorial work.

RIGHTS of the oil men in the lands withdrawn by presidential order in 1909, are at last to be tested in the courts through a friendly suit instituted by the Attorney-General. This is the only sensible method of determining the matter.

NOT wishing to detract attention, but every square foot of Canada having, we understand, been 'presented' to the Canadian Mining & Exploration Company, we merely remark that the charter of the company does not forbid investment south of the line.

AUSTRALASIAN engineers recently visited Cobar in connection with the annual meeting of the Australasian Institute of Mining Engineers. One of the interesting features of the meeting was the presidential address delivered by Mr. H. C. Bellinger. His many friends in this country will, we are sure, be glad to read the abstract printed on another page.

SO many inquiries have come to us regarding the International Society of Mining Accountants, recently formed in Detroit, that we take this occasion to say that Mr. W. H. Charlton, 46 Hooker avenue, Detroit, is the secretary of the organization and will gladly answer inquiries as to its scope and purpose. Standardization of mine accounts has been much discussed by engineers, and it is to be hoped the accountants will take up the matter and bring it to some definite conclusion. We wish the new society success in full measure.

THE recently announced investment by Mr. Charles M. Schwab and associates in the Loretta mine, aside from its interest as promising the development of a new large copper producer for California, is worthy of note as illustrating two important phases of present-day mining; first, the length of time and amount of labor required to develop a prospect into a mine; second, the vast outlay of money required to change a developed mine into a producer, especially when the property is low-grade, and large quantities of ore must be handled on a narrow margin. The future of mining undoubtedly will be along the lines of other industries. Men and companies with strong financial backing and with modern business methods will replace the prospector and individual owner. The romantic vision of the miner with gold-pan and burro, searching the hills for a flood of sudden wealth, will fade away, to be replaced by a picture of cold commercial transactions leading slowly but surely to ultimate gain. The spectacular side of mining

will be the loser, but the industry in the end will rest on a firmer basis, one which will invite conservative attention and investment.

**A**MONG minor results of the revolution in Mexico was the interruption of the work of the Mexican Institute of Mining and Metallurgy. Not even a quorum attended the annual meeting, and matters came to a standstill. Fortunately this but served to call needed attention to the excellent work of the Institute and under guidance of a committee consisting of Messrs. J. B. Empson, P. A. Babb, J. M. Nicol, and G. A. Denny, a vigorous campaign has resulted in putting the organization on a good financial basis and assuring an early resumption of the publication.

**E**CUADOR is the least known and least developed of the South American countries facing the Pacific, despite its rich mineral resources. One reason is that Guayaquil, the principal seaport, has a well deserved reputation for unhealthfulness that unjustly condemns the whole country to foreigners. It is now announced that the city is to be entirely reconstructed, and when it shall have become as sanitary as Panama and Havana, the region back of it, easily reached by railroad, will attract many tourists, and so come eventually to be developed. We present this week an outline of the geology of the country which indicates a wide region in which the opportunity for finding gold is excellent. At present the only important gold mine belongs to the South American Development Company, an American corporation, for which Mr. John W. Mercer is manager. While little information has been made public, it is known that the veins in the andesite, worked by this company, have paid well. There are many old placers in various parts of the country, and in the unsettled provinces, where as yet the Indians interfere with prospecting, there is virgin ground.

### Railroad Mineral Lands

Mineral lands and railroad grants are a perennial source of trouble throughout the West. The cry for rapid development led, some years ago, to generous allotments of land to companies that would undertake to build transportation lines. Haste bred carelessness, and, too, a quarter of a century ago neither in public nor private life was it as customary to defer to the expert as now. With rare exceptions it was not the intention of Congress to give to the railroad companies any mineral lands other than those containing iron and coal. Such lands were given on the basis that these minerals were needed in the construction and operation of railroads, though we do not remember of any blast-furnace having been erected on the public land to make pig iron for a railroad. However, the exception was on a par with the general rule permitting a settler to cut timber from public land for the purpose of building his home, and no great harm resulted from it. The whole policy, though, was one designed to bring settlers upon the land and increase the farming population, rather than to parcel out the national wealth. Unfortunately, in a number of cases the grants went to promoters who failed, and considerable areas of public land passed to private corporations, a very different thing from passing to individual settlers, without any substantial improvement in transportation facilities. More serious still was the fact that in the rush there was no adequate study and classification of the land. In individual cases there was even rank dishonesty, but in general it is fair to impute the mistakes to haste and lack of knowledge. When Mr. Hoke Smith was Secretary of Interior the custom was introduced of writing into the patents the words of the original grant excepting 'mineral lands,'

and the force of this exception is still in dispute. It is held, on the one hand, that the companies accepted thereby a limited patent, and that the same force that made the patent valid also made the exception binding. On the other hand, it is contended that specific patents were given to specific pieces of land, and that, in the absence of evidence of fraud, the classification made by the Government by the act of giving patent, became binding upon itself. Furthermore, it is not in accord with sound public policy to disturb titles except in case of real necessity. Subordinate courts have given conflicting decisions, but certain phases of the contention have never been passed upon by the United States Supreme Court. There seems little question that if 'mineral in the land' had been specified, the exception would be binding, but how 'mineral land' is to be construed is less certain. The equities in these cases are by no means all on one side. In the instance of oil lands it is worth remembering that the oil is principally valuable for fuel and that the original grant contemplated giving the railroads coal lands, coal being then the only known fuel of importance.

The Government is now contesting the right of the Southern Pacific Railroad Company to oil lands in the San Joaquin valley, though in this case the allegation of fraud enters into the matter. In the case of the railroad laws in southern Oregon and northern California, the case if taken into the courts, will determine the main question as to the force of the excepting clause in the patents. At the meeting last week at Yreka of the Southern Oregon and Northern California Miners Convention, a vigorous demand was made for action by the Government in contest of the railroad titles. This was all the more interesting since careful plans had been made to smother any such discussion. Naturally our sympathies in this case are with the miners. We should like to see the great mineral region to the north opened to vigorous prospecting. The situation has worked out to substantial injustice, and the railroad undoubtedly holds lands which Congress never intended to give. This is not sufficient reason for taking them away if they legally belong to the present holders, but if there is a cloud on the title it is to the interest of everyone to have the matter promptly and fully presented to the courts and fairly determined. In the meantime we are glad to note that by order of the Secretary of Interior all future applications for patents under grants are to be held until the Geological Survey shall have examined and classified the lands. This will not altogether preclude mistakes, but the best available information will be utilized, and it is better to go slowly than to run into endless litigation.

### Excursions of the Institute

One of the enjoyable and interesting features of the work of the American Institute of Mining Engineers has been the excursions that have been arranged as incidents to certain of the meetings. In its wanderings, the Institute has held meetings from Germany to Japan, and from Panama to Dawson. Not to delve too far into ancient history, the principal excursions of the last six years have been as follows: London, 1906; Toronto, 1907; Chattanooga, 1908; Spokane, 1909; Canal Zone, 1910; San Francisco and Japan, 1911. The excursions have been uniformly well arranged and well conducted; participation in them has been both pleasant and profitable, and many strong friendships have been formed at the same time that professional solidarity has been greatly augmented by these journeys in company. In early days when railway transportation and other concessions were freely given, the expense to each member of the party was materially less than on a private journey. In recent years it has been higher, but averaging neither greatly more nor less than the same per-

sons would probably have paid in traveling alone.

For many years the Institute refused to fix any permanent headquarters, and its office was wherever the secretary lived; its home was wherever a group of members got together. The first excursions were strictly incidental to the meetings. The latter were generally held in the East where distances were small. It is interesting to note that, of the first thirty-three meetings, only one was held west of the Mississippi—the eleventh, which was at St. Louis in 1874. It was not until eleven years after the Institute was founded that a meeting was held west of the Great Plains, Denver in 1882 being the first of the mountain cities to entertain the Institute. So long as the journey to and from the Institute meetings occupied but a few hours, and excursions during the meeting were to nearby points, the arrangements were simple. Such friends as could, arranged to travel together, but there were no special trains and no elaborate receptions. When meetings came to be held frequently in widely separated cities, it became customary to organize formal parties to make the journey from the East to the meeting point and return. At first negotiations were conducted with one of the tourist agencies to care for these parties, but these negotiations came to nothing, we are informed, because of the unwillingness of the agency to make a sufficiently flexible arrangement. With a widely scattered membership, it was necessary to provide for those who might wish to join or drop out en route. To carry on the business properly it was also necessary to contract in advance for transportation, sleeping-cars, supplies, and hotels, and this involved a financial responsibility that it was considered unwise for the Institute to assume. Accordingly, the business fell to some private individual, usually the assistant secretary, who assumed the risk, did the work, and took what profit, if any, resulted. The work was well done, and the excursions have been eminently successful. The announcements have not always been as clear as was desirable, and there has been some misunderstanding of the conditions. Many members have assumed that the excursions were conducted as a part of the work, if not of the business, of the Institute, and that the officer in charge labored more in the spirit of accommodation of his fellow-members than for any personal profit. The fact that intending participants were required to pay considerable sums in advance was commonly supposed to sufficiently guarantee him against loss; especially since there was no express agreement to return any of this money in case the member found it impossible to attend. As a matter of fact, such prepayments have sometimes been returned and sometimes not. There has never been any public statement of the finances of these trips, though the amount of money involved has run into thousands of dollars, and by the public at large as well as many if not most members, they were considered Institute affairs. Whether there was ever any loss is not known; certainly none has been mentioned. That there was profit in certain cases is, on the contrary, well known. In the case of the excursion of 1911, conducted by the secretary, the accounts were audited, at his request, by a special committee of the Council, which reported that the profit was not unreasonable, taking into view the risk, the work, and the loss of salary while participating in the excursion.

The Committee of Five which has been investigating the affairs of the Institute, has commented at some length upon the excursions. They point out that, despite the fact that as business affairs the excursions were privately conducted, and that they have presumably been a source of personal profit to those in charge, the Institute itself has shouldered considerable expense in this connection. Since 1904 this has averaged nearly \$1000 per year, and covers the expense

of assistants especially employed in connection with the excursions, in addition to incidental expenses of postage and for circulars, some of which has fallen on the Institute. No one doubts the propriety of the Institute assuming the expenses of the secretary in attending its meetings, and the more he travels around and meets his fellow-members the better they will be pleased; the committee points out, however, that in certain cases as many as three persons were taken on these excursions, charging expenses and salary to the Institute, and some of them, at least, at the same time participated in the profits of the trip. This circumstance illustrates how difficult and unsatisfactory the present arrangement is. Another feature that has invited adverse comment is that, since the profit to the manager depended upon the number participating, invitations have been extended rather widely. Of the total number taking part in the excursion it has happened that only a minority were actually members of the Institute. This works out badly, since such parties are always entertained as members of the Institute. Mines and works are open to them, and possibly special rates are conceded, that would not be given to a personally conducted party of ordinary tourists. The Institute has been uniformly fortunate in its guests, but local committees have at times been embarrassed by the number of non-technical excursionists, and the tendency to overemphasize the social features of the affair has undoubtedly been intensified.

For all these reasons the committee recommends that for the present the Institute abandon the policy of making long excursions, and that when they be resumed their business management be entirely divorced from the Institute. While sympathizing strongly with the attitude of the committee, we are not prepared to entirely endorse either recommendation. It is probably just as well not to plan a long trip this or perhaps next year, but we do believe that the excursions to various parts of this and other countries are a proper form of activity for the Institute, and that they can be so conducted as to eliminate the few features that have been criticized without risking the loss of their main good features—the opportunity for members of the Institute, and perhaps the members of their immediate families, to get well acquainted with other members and other regions than those that they constantly see. Desirable as local sections are, they can not be substituted for the broad acquaintance that the excursions make possible. That relatively few participate is less of an objection than it seems, since in the aggregate a considerable number do actually join each excursion and local members all along the route have the opportunity of meeting the whole party. What is needed is a different organization of the business end of the excursion. The manager should be guaranteed against loss and paid reasonably for his services, but it should not be so much of an object to him to enroll participants as would lead to making the guest list unduly large. While it should go without saying that no officer of the Institute should be in a position to make money out of his fellow-members by virtue of his position as an officer, the Institute itself can not escape responsibility for the excursions if they take place at all. Rightly or wrongly, they will be considered Institute affairs, as we believe they should be, and the Institute will be held accountable for their conduct. People who entertained these parties have always supposed they were extending a courtesy to the Institute, and doubtless they will continue to do so. The excursions should, we think, be continued, and should be more closely identified with the Institute, subject in fact to the control of the Council, instead of being further divorced from it and made sources of personal profit or loss.

# The Pennsylvania Smelting Company Plant

By S. L. GOODALE and H. C. RAY

This smelter occupies a plot of about fifteen acres at Carnegie, Pa., on the Pittsburg, Cincinnati, Chicago & St. Louis railway, eight miles west of Pittsburg, the general office of the company being at the latter place. It was built by former employees of the Pennsylvania Lead company, which was a pioneer in the smelting and refining of lead silver ores, but which was dismantled at the formation of the American Smelting & Refining Co. The plant has been enlarged from time to time as business increased, so that the

lead bullion is desilverized by the Parkes process, after the usual softening, and the silver refined by cupelling. The ultimate products of the smelter are fine silver, high-grade desilverized lead, and antimonial lead as a by-product. High-grade assayers' test lead and litharge are produced. The supply of ores comes from widely separated districts, and varies greatly in character from time to time. Silver ore is obtained from the West and from the Cobalt district of Ontario, only the richer ores of the latter district being

SOFTENING FURNACE.

BLAST-FURNACE FEED FLOOR.  
TILTING FURNACE.

arrangement is not so convenient as could be made in a plant all designed at one time. This lack of a general plan is not very serious, however, because the tonnage treated is high grade and not so large in amount as in Western plants.

The smelting of high-grade lead and silver ores constitutes most of the work of the plant. For the smelting of sulphide lead ore, the method known as iron reduction is in use. An amount of metallic iron sufficient to take up all sulphur present as matte is added to the blast-furnace charges. The sulphur is then eliminated by roasting the matte thus formed, which is essentially an iron matte, as copper is usually present to only a very small extent. The roasted matte is used to partly supply the fluxing requirements of a later charge. The metallic iron is added in the form of the cheapest scrap obtainable, such as tin-plate trimmings and other material not usable in the steel mills, but as good or even better than any in this connection. Details of the blast-furnace construction are given below.

For the smelting of extremely rich silver ores, a special reverberatory furnace method is employed. All the silver-

treated, and being classed as 'high' and 'medium' grade. In addition to ores, various lead-bearing industrial by-products or wastes are treated.

Gas, coal, and coke are the fuels used. Natural gas, costing about 20c. per thousand cu. ft., is used for retorting, assaying, and lighting. Coal, obtained not more than two miles distant, is used for power, and for most of the metallurgical heating except in the blast-furnaces. Coke is produced in four beehive ovens, situated on the feed-floor level and near the main switch from the railroad. For each charge in each oven, 48 hours is required, this length of burning resulting in a satisfactory coke. A coking plant at a lead smelter is unique, although common in the case of iron blast-furnaces. No mechanical appliances for handling coal to the ovens or coke from them are provided; because for such a small number of ovens wheelbarrows are cheaper.

There are two rectangular, water-jacketed blast-furnaces, 36 by 108 in. at the tuyeres. Each side is made up of six cast-iron jackets, each 17 in. wide and 49 in. high. There are six 3-in. tuyeres on each side of the furnace. The jackets measure 20 in. from the bottom to the bosh-line,

and the bosh is rather flat. There is no end-bosh. The furnace end is closed by two cast jackets, each 23½ in. wide at the bottom and tuyeres, and 30 in. wide at the top. The opening for the slag spout is 14 by 14 in., and only the opening in one end of the furnace is in use. The water-jackets are held together by bolting them through lugs cast on the plates, the cracks between being tightly luted with fireclay. The bustle pipe is 15 in. diam. and encircles the furnace; blast is led from it by canvas pipes terminating at the tuyeres in sheet-metal pipes simply thrust into the tuyere openings in each jacket. The blast-pressure is about 16 oz. The jackets rest directly on the brickwork of the crucible, which is bound by a heavy steel plate with butt-riveted joints. The crucible is elliptical in plan, large enough to contain the lead well on either side. The brick shaft above the jackets is supported by steel channels, resting on cast iron posts, 7 ft. 6 in. high at each corner.

The charging doors for one furnace are two in number; one on one side, occupying about half the length of the furnace, and the other on the opposite end, occupying practically the whole end. The charging-doors for the second furnace are on the sides and diagonally opposite each other. The doors are simply sheet metal pieces resting against the furnace, and raised for charging by chains with a counterweight. As the furnaces are small, the charge is easily spread evenly through these charge openings, which are placed in the unusual positions for convenience of access on the charge floor. Horizontal flues lead the gases to a down-take just outside the building, which accommodates both furnaces. From that point the gas goes through an underground flue of small size to the regular dust flues, in which dust is dropped mainly by frequent alteration of the direction of flow of the current of gas. The total length of the flues is approximately 500 feet.

The charges are wheeled in barrows from the bins or the stock or coke yard to the furnaces, each barrow load being weighed on a platform scale. The coke and stock yards are just outside the building on the feed floor level, and the bins in a line in the building, the most distant bin being probably within a hundred feet of the furnace, so that transportation of charges to the furnace is a simple matter and relatively inexpensive. The bedding system is not used, and, in fact, the ore storage capacity is somewhat limited.

The furnace charge varies greatly from time to time, because of the large number of materials smelted, and their diversified composition. Of coke, 12 to 15% is used, the amount being kept near the higher figure most of the time. The amount of lead on the charge is variable, and ranges from 10 to 20%, the latter proportion being reached when there are large quantities of drosses, old litharge, etc., to be worked up. The slag is maintained at about the following composition: SiO<sub>2</sub>, 32%; FeO, 34%; CaO plus MgO, 17 per cent.

The products of the blast-furnaces are a lead bullion, a nickel-cobalt speiss, an iron matte, and the slag. The bullion overflows from the siphon tap into a collecting iron pot, and from there is ladled into molds by a workman, who also attends to keeping the tuyeres open. The ordinary run of bullion contains from 80 to 800 oz. of silver, and little or no gold. The speiss, matte, and slag are tapped together intermittently into small slag-pots which are run, as soon as cool enough to move, to a settling furnace about 150 ft. distant. The top crust is broken and the liquid material is poured into the settler. The slag shells are broken and re-smelted as usual.

The settler is a small single-chamber—that is, with no bridge-wall—reverberatory furnace fired with natural gas. It is 10 ft. long and 6 ft. wide outside, with walls 1 ft. thick. The bottom is a sheet steel box, resting on rails, in which the hearth proper is built up of brick set in clay, and with a final lining of clay and sand tamped in over the brick. All the refining, melting, and softening furnaces are provided with a similar steel under-pan to prevent any lead that may penetrate the brickwork from being lost in the earth. The settling furnace is tied together with rails for braces by means of round iron tie-rods. The slag, matte,

and speiss are poured in the top through a hole that is covered except when pouring. The top of the settler is on the level of the tapping-floor of the blast-furnaces; and the separated products are wheeled from the settler on a level about 5 ft. lower out to the dump, where the pots are left to cool off. There are three tap holes in the front side of the settler; one at the level of the hearth; another, the matte tap, 10 in. higher; the third, the slag tap, 3 in. above the matte tap.

In operation, the settler is heated prior to charging, and when at the full heat is filled with slag, etc., as it comes from the furnace, until filled above the level of the slag tap-hole. The bath quickly settles, the slag rising to the top, and below that, matte, speiss, and, at the bottom, any lead that may have been entrained. Slag is drawn from the settler intermittently until matte shows at the slag tap-hole, when the matte is drawn from the lower hole until slag shows. The slag is then sufficiently free from matte and speiss to be thrown over the dump. The pots drawn from the matte tap contain matte and speiss, which separate well in the pot, and when cool are broken apart. Slags from the melting of extra rich charges are smelted again in some low-grade clean-up run. The speiss contains silver, and is desilverized by re-smelting. At present the desilverized speiss is otherwise a waste product. The re-smelted speiss consists mainly of iron, but contains up to 1% of cobalt and nickel, the former predominating. It is low in other metals of value.

The matte is crushed to ¼ inch in an 8 by 10 Blake crusher placed on the lower level of the plant, close to the blast-furnaces and in the same building. It is then roasted in hand-rabbed reverberatory furnaces, the sulphur being reduced to about 4 to 6%. The roasted matte is used in the blast-furnaces as iron flux, copper accumulating so slowly that it is only at intervals that matte is made sufficiently rich to be sold for its copper content. There are three roasting furnaces, placed in a separate building near the blast-furnaces. They have a hearth area of 40 by 14 ft., with 12-in. walls; and a firebox or grate area of 7 ft. 4 in. by 4 ft., and are of the ordinary hand-rabbed type. The fuel is a local long-flame coal. No ore is roasted in regular operations.

The lead from the blast-furnaces is softened in reverberatory furnaces having a hearth area of 9 by 12 ft., with 4 by 6-ft. grate area. There is a water-cooled under-pan of steel plate construction, lined with brick to form the hearth. The softening occupies from twelve to twenty-four hours, the bath having to be skimmed several times because of the antimony present. The soft lead is run direct to the large kettle of the desilverizing set of three kettles. This kettle is cast iron, 7 ft. 7 in. top diameter, and of shallow bowl shape, with a firebox directly underneath, using coal for the heating. The lead bath is given three or more zincings, each addition of zinc being skimmed before the next is added. Agitation is accomplished with a steam jet. The first, and sometimes the second, crust goes to the retorts after being thoroughly drained of lead. The last, and sometimes the second, crust is saved for the subsequent first zincing of another lot. The disposition of the intermediate crust depends on its richness. The two smaller kettles of the zincing set are 3 ft. 10 in. and 3 ft. diam., respectively, heated as is the large one. The retorting is done in a Faber du Faur gas-fired retort furnace, of which a view is shown. One charge amounts to about 1000 lb., and there is usually left in the retort after driving off the zinc some 800 lb. of rich lead, called 'retort riches.' The retorting occupies five hours, and the zinc recovered is used over again. The retort riches are then poured into molds and are later cupelled as described below.

The desilverized lead from the large zincing pot is then run into a final softening furnace. The zinc and other impurities are slagged off or burned out, and the purified lead run from the furnace by an iron pipe with a swivel joint just outside the furnace. The valve and this joint are kept hot by a small gas jet. The stream of lead is conveniently run to a series of molds set in a semi-circle about the front

of the furnace. The smelter has a duplicate equipment of the softening and desilverizing furnaces or pots. Antimonial skims from the softening are saved up until sufficient has accumulated for a hard run. A considerable amount of this hard lead is made, as there is a strong demand for it.

The retort riches and other rich lead are cupelled in English cupelling furnaces. The tests are roughly elliptical, built up on a cast-iron plate inside a heavy rim or ring, open at one point in front for a pouring spout, this opening being bridged by a casting. The plate is supported at the back by stirrups resting on a rod and at the front is hung by chains from a triplex chain-block so as to regulate the pouring. The test is made up with a lining of cement and ground fire-brick, tamped to shape, and with a pouring spout at the front side. An air-blast strikes across the surface of the bath from the rear, thus driving the litharge as it forms toward the spout, and during the operation the litharge is run off continually, except for the time occupied in changing the pots to receive it or when charging additional lead. This litharge is re-smelted. The test is covered or roofed over with a fixed firebrick arch built with a slope to direct the heat against the bath.

The silver from the cupel is run into a granulating tank through which a rapid stream of water flows during granulating. The silver is then melted in one of the Faber du Faur furnaces and cast into bricks weighing about 1100 oz. One cupelling furnace is reserved for the making of C. P. or silver-free litharge, and is run in exactly the same manner as the above, except that pure lead is used in the charge. This litharge is then ground dry, in a ball-mill, and then sacked or put up in barrels for shipment. Test lead is made by pouring the melted lead into an iron cylinder in the bottom of which are two holes of about  $\frac{1}{16}$  in. diam. The lead running through these small holes is struck by a blast of compressed air and granulated, being caught in an iron-lined box. This treatment gives a high percentage yield of the lead in a suitable condition for the uses to which test lead is to be put. The test lead is necessarily screened to remove all oversize.

## Report of the Committee of Five

Below is presented a summary of the report of the Committee of Five, consisting of J. F. Kemp, C. R. Corning, George C. Stone, W. H. Nichols, Jr., and A. R. Ledoux, appointed at the February meeting of the American Institute of Mining Engineers to consider the affairs of the latter and the proposed amendments.

1. The Institute has been running behind \$2000 per year in ordinary net income, and \$7884 more if the land should be paid for in equal annual instalments plus interest.

2. Prior to this year, the technical, social, and business affairs have been practically under a one-man management. This is generally undesirable, and has become impossible in a society of our present size and diversified activities, and should be changed.

3. The publications have been admirable and of high standing, and we would deprecate any change in type, printing, paper, or other literary characteristics, and we suggest that each year, in the Year Book or other prominent part of the publications, all three fundamental documents underlying the Institute be published—not only, as heretofore, the Constitution and the By-laws, but the Certificate of Incorporation as well; but we believe that the cost can be materially reduced by reductions and adjustments, even in addition to those which the Directors and Council have inaugurated in 1912, so that a saving of over \$5000 can be effected in this line.

4. We have indicated in the body of the report other savings in expense through greater efficiency, prompt adherence to office hours, and otherwise.

5. The Committee has given in detail its views and its reasons for recommending the legalizing of the office of Secretary Emeritus, and will later, as part of the proposed

changes in the Constitution and By-Laws, point out the steps necessary to that end.

6. The putting into effect of recommendations as to a reduction of salaries of Secretary and the retired Secretary, if continued, and of editorial expense with other economies elsewhere suggested, we believe would bring down the deficit very largely, or entirely eliminate it. We believe, in brief, in cutting all expenses and all operations likely to involve such, to the absolutely necessary minimum to make the budget of the Institute, all financial obligations of whatever nature included, balance.

7. We advise that the Annual Meeting, which has now been adjourned until October, shall take up and carefully consider suggested alterations in the Constitution, that such of them as meet the approval of the membership may be put into effect at the Annual Meeting of 1913.

8. We urge the Board of Directors likewise to inaugurate, as soon as possible, amendments in the By-Laws, so that responsibility shall be distributed and not placed upon one individual, and to put into effect still further improvements in addition to those already inaugurated by the Directors.

9. We recommend the copyrighting of all papers accepted and printed.

10. We advise that delinquent members be dropped after twelve months' delinquency.

11. We recommend that the election of life members be limited to 5 per cent of the actual membership, and that the receipts from life memberships be set apart toward the accumulation of a fund for the liquidation of the mortgage and interest thereon, and not turned into the general fund of the Institute to meet ordinary expenses, and that after the indebtedness be lifted they be invested in trust funds and the interest thereon used to meet the Institute's obligations to its life memberships.

12. We suggest for serious consideration the postponement of the publication of the 'Emmons Volume' unless the Directors and Council are satisfied that there will be such a demand for it as immediately to meet the first expense of, say, \$2100, which we understand will be payable next fall.

Finally, we wish to express our absolute confidence in the continued value of the Institute to all of its members; our conviction of the possibility of its greater efficiency, until its publications become indispensable to the profession and membership a coveted honor. We urge the present membership to increased interest and coöperation, so that as soon as possible proposed constitutional changes may be intelligently discussed and properly authorized, and we record our fullest confidence in the Board of Directors and Council as at present existing, which have already initiated many important changes in methods and have continued to great advantage their efforts since the last Annual Meeting. Due credit should be given to those of our members who have consented and who shall consent to accept offices whose duties are and will be no sinecure, if our recommendations are adopted. The membership should keep itself informed as to the affairs of their society, and by attendance and discussion at meetings and otherwise, inquire and criticize and be assured to their satisfaction that the business, both technical and financial, is conducted by modern methods and in a manner to insure prosperity.

Summing up, therefore, concerning the specific questions entrusted to us for consideration, we recommend:

(a) That the vote on the constitutional amendment to change the name of the Institute be kept open for careful consideration and decision in 1913.

(b) We recommend a negative vote upon the amendment proposed last February authorizing an increase in dues, believing that the economies proposed, some of which are already in effect, will not only do away with the deficit, but provide an adequate income, possibly even providing sufficient funds to liquidate the mortgage.

(c) We recommend a negative vote on the proposal to reclassify retroactively the present membership, leaving any reclassification of membership for a more careful consideration later on.

# The South Belt at Rossland, B.C.

By C. A. STEWART

The mineral output of Rossland, British Columbia, comes entirely from a group of veins lying north of the town, among which the Le Roi, Centre Star, the War Eagle, and the Josie are the most important. Despite the success of these properties and the widespread mineralization in the district, little or no attempt has been made in late years to open up other mines, largely because the district has not yet recovered from the loss of confidence resulting from unscrupulous promotion in its early days. In view of this fact, it is interesting to note that attention is now being given to a series of claims south of the town known as the 'South Belt.' A discussion of these deposits may well be preceded by a summary of the geology of the whole camp.

This district has been mapped by Messrs. Brock and Young of the Geological Survey of Canada. The oldest formation is the Mt. Roberts series of quartzites and slates of Carboniferous age. This has been intruded by a complex series of Carboniferous and Tertiary eruptives, of which monzonite and augite porphyry are the most important, both in areal extent and in their relation to the ores. Basic dikes are numerous and are often asso-

SKETCH SHOWING RELATION OF VEINS ON THE RICHMOND PROPERTY, ROSSLAND.

ciated with the veins. So extensive has been the intrusive activity, that the quartzites and slate are cut up irregularly, and often form island-like masses in the greater areas of igneous rocks. The veins now being worked north of the town are the result of replacement along a series of small crevices in either the monzonite or the augite porphyry. The ore minerals are pyrite, pyrrhotite, chalcopyrite, and occasional arsenopyrite, and the gold seems to occur most abundantly with the chalcopyrite. Extreme variations in width are common, and often a mere stringer of sulphides that would attract no attention elsewhere will be followed long distances and found to open out into wide and rich deposits. The geological features affecting this variation have not yet been determined. There is practically no oxidized zone in the district, and secondary sulphides are not important.

The South Belt properties are about two miles south of the present producing mines, and include both prospects long idle and newly discovered croppings. They differ from the veins north of the town in having quartzite for wall-rock in several instances, and in containing galena with high silver content. Particular attention is being paid to the Richmond and Bluebird properties, both of which are in the quartzite, and preparations are being made to do active work on them during the summer. While the Bluebird veins were discovered several years ago, the Richmond is a comparatively new prospect, and a detailed description of it will serve to illustrate the general occurrence.

As shown on the accompanying sketch, veins have been found, and a cross-vein approximately N. 40° W. and a dip 70° N have been exposed by trenches for several hundred feet, and two test-shafts have been sunk. A summary of occurrences as exposed by these shallow workings follows, the results of the assays being those kindly given me by Mr. Coulter of Rossland. All of the veins are of the replacement type, the gangue being the unreplaced remnants of dense quartzite. At A there is a 3-ft. vein of pyrite and chalcopyrite assaying from \$2.50 to \$4 in gold. The 'main vein' at the shaft, which is not over 30 ft. deep, shows 4 ft. of ore—pyrite, pyrrhotite, chalcopyrite, and galena. The last-named mineral is irregularly distributed, and where it is present silver to the amount of 20 to over 100 oz. per ton has been found. The gold in galena-free portions varies from \$3 to \$4 per ton. North of the main vein, at B, are two narrow pyritic stringers, not over a foot wide. At D these showed \$12 in gold. At C is a series of three veins of pyrrhotite and pyrite which have been regarded as the continuation of the Bluebird vein, but there is at present no geological basis for such a belief. The cross-vein at E is about three feet wide and is largely pyrite and chalcopyrite. The shaft on this vein is down 30 ft., and from it a cross-cut is said to have been run for 27 ft. without reaching either wall, and a high gold content is reported. At the time of my visit, in the early spring, the shaft was flooded, and I was unable to verify this statement.

Three-quarters of a mile northeast of the Richmond is the Bluebird, on which more underground work has been done. Galena is an important ore-mineral on this property, and a high silver content has been reported. Near the Bluebird are several idle properties, the dumps of which show much galena and some sphalerite.

In connection with these South Belt veins two geological problems arise: (1) the explanation of the presence of the galena which is so much more abundant here than in the north, and (2) the probable effect of the quartzite on the permanence of the veins. I am not inclined to regard the galena as the result of any form of surface alteration, and I do not believe that its occurrence will be directly related to depth. Its distribution is likely to be as irregular along the strike as on the dip, and only further exploration will settle the question of its abundance. Surface indications, however, give reason to believe that lead-silver ores are a more important factor in the South Belt than in the north. According to the generally accepted theories of ore deposition, the dense quartzite would be a less favorable place for replacement veins than the basic igneous rocks of the district. General theories, however, must be abandoned when in conflict with facts, and it cannot be denied that at the Bluebird and the Richmond the quartzite has been replaced extensively enough to warrant further exploration. The brittle quartzite seems to have been broken into a series of closely spaced, parallel cracks, along which the ore-bearing solutions have come, eating out into the rock and replacing it. It must also be remembered that views in regard to replacement are undergoing a change, and that new discoveries are constantly showing extensive replacement under conditions formerly regarded as unfavorable. The fissuring at the Richmond seems to be independent of the bedding or the joint systems of the quartzite, and to be the result of the same forces that produced the veins to the north.

Experience in the older mines of the district should be considered by those having to do with further work on the South Belt. These properties at present are only prospects, and exploration should be undertaken with the expectation that lean stringers and bonanzas will alternate here as in the north of the camp. In fact, the value of the ore may be even more irregular than in the older mines, for the composition of the quartzite will vary from bed to bed, and may have an influence on the width and richness of the veins.

# The Associated Mill, Manhattan

By J. C. KENNEDY

The Associated mill at Manhattan, Nevada, is owned by the Manhattan Associated Milling Co., of which John G. Kirchen is president. The mill was designed and erected under the supervision of Charles Kirchen, who is general manager for the company; R. W. Marston, formerly of the Tonopah Extension mill, is superintendent. Construction was begun late in November 1911. The usual, or greater than usual, number of delays occurred in getting in machinery and construction material during the winter season, but the mill started running April 1, 1912, the day set. Less than the usual amount of trouble occurred on starting the mill, which speaks well for the experience and skill of L. A. Blackwell, the millwright and foreman in charge of construction and installation of machinery.

The principal stockholders of the owning company are interested in the nearby White Cap, Steffner Consolidated, and Mushett leases. The mill is so situated with reference to the leases mentioned, as well as the Kendall & Douglas, on the Manhattan Consolidated, the Swanson lease on the Earl, and the Bath Bros. leases on Litigation Merger and Earl, and the workings of the Manhattan Amalgamated Mining Co., that the output of all these leases and properties can easily be sent directly to the main upper sampling floor of the mill. So far, ore from the Steffner and the Mushett leases has been trammed to the mill, while that from the White Cap has been brought in large ore-wagons, mainly on a down-hill grade. Ore-bins delivering to cars on the tram track are erected outside of mill for different lots of ore. The mill is designed for general custom work in the district in addition to milling these ores, and for that purpose a fairly complete automatic sampling system has been installed. Ores will be bought and paid for in small or large lots after sampling and assay. This is a new departure in custom milling in the district which is pleasing and beneficial to sellers of small lots of ore, and contributes toward lower milling costs by avoiding delays for frequent clean-ups and consequent waste of time and labor. It is said that unusually low milling rates for this section are offered to owners of small lots of low-grade ore. So far the mill has had an abundant supply of ore from two or three of the leases, and this seems to be the outlook for the immediate future.

Fresh water for the mill is collected in a 20 by 16-ft. wooden tank, placed at such an elevation above the mill as to give a pressure of about 75 lb. at the filter floor for discharging the cake. This water comes mainly from workings of the Steffner and White Cap leases. Owing to the light winter rainfall, the water supply is rather short at present; but as the greatest depth yet attained at either lease is only about 200 ft., no anxiety exists for the future. In a well in the gulch below the mill, water is collected from the drainage of the tailing ponds and pumped to the mill to reinforce supply. Other sources of supply are easily available.

The ores of the White Cap, Steffner Consolidated, and, to a less extent, that from the properties and leases farther west on the mineral zone, while apparently fully oxidized, are refractory. The White Cap ore only yields on the plate about \$1 per ton from ore \$50 or higher in value, and the Steffner ore not much more. Much of the gold is in a very fine state, coated in some manner which would indicate the necessity of fine grinding. A recently discovered ore-shoot in the Mushett lease, however, carries much coarse native gold in reticulated and crystalline forms. The White Cap ore contains a small amount of cinnabar and other sulphides. The Steffner ore contains sulphides of antimony and arsenic. These sulphides have so far not proved objectionable as cyanicides.

There are two steel storage tanks, 9 by 14, and a wooden tank, 12 by 16 ft. The solution is kept at a strength of about

1.5 lb. KCN per ton. The main upper or sample floor of the mill is provided with steel plates for coning and quartering down large samples. The southeast corner of this floor is partitioned off as a room for crushing, pulverizing, and otherwise preparing samples for assay. The assay laboratory itself is in the office building a short distance from the mill. The ore is first weighed and then dumped about 4 ft. to mouth of crusher, with no intervening grizzly. The crusher is of the Foster type. With the ores so far handled, which have a considerable percentage of friable and earthy matter, the capacity of the crusher is fully 50 tons in an 8-hour shift.

The travel of ore and solutions through mill are shown by the accompanying flow sheet. The crushed ore is raised

FLOW-SHEET, ASSOCIATED MILL, MANHATTAN.

by an elevator to an automatic sampler of the Vezin type, which cuts out a 1/20 sample, the reject falling directly into a flat-bottomed ore-bin of 80 tons capacity. The sample passes to a set of rolls, thence to a second Vezin sampler, which takes out 1/10 for a final sample, which falls into a receptacle in a locked compartment at the end of battery bin. The reject falls directly on sampler floor, is transported in cars, dropped through the crusher when not in motion, elevated, and dropped into the battery-bin. Crusher, elevator, rolls, and sampler are driven by a 30-hp. motor. The ore is discharged from the bin through the usual rack and pinion gates to suspended Challenge feeders to the mortars of a 10-stamp Hendy mill, driven by a 30-hp. motor. The

stamps weigh 1050 lb., with from 7 to 7½-in. drop at the rate of 100 drops per minute. The mortars are of the narrow quick-discharge type. Battery posts are large, and the concrete battery foundation and battery-frame are of the strongest and most substantial construction. All foundations in the mill are of concrete and of good size. Screens of 30 mesh or finer are used. The Tyler top-cap No. 50 is used for some ores, and the No. 273 for harder ores.

The pulp goes to a 30-in. by 15-ft. Akins classifier placed adjacent and parallel to the tube-mill and set on a slope of 2½ in. to the foot. The tube-mill is 4½ by 16 ft., with scoop feed, and is driven at 25 revolutions per minute by a 50-hp. motor. The discharge from the tube-mill goes to the classifier and the sand is returned to the tube-mill, thus forming a closed circuit; all the material traveling around the circuit until brought to such a fineness that it passes off in the overflow from the classifier. The tube-mill is provided with the Komata liner, which is rare and recent in Nevada, its previous use, so far as I know, being confined to the Goldfield Consolidated and Tonopah Extension mills. One of its features of merit is that it has a larger effective inside diameter for a given outside diameter, compared with silex blocks or other lining. Another is that the inside diameter varies less during its life, making the peri-

ASSOCIATED MILL, WITH THE STEFFNER, MUSKETT, KENDALL AMALGAMATED, AND EARL MINES IN THE BACKGROUND.

pheral speed more constant, an important consideration. It is claimed that a less depth of loading with pebbles is required, the practice in New Zealand being to keep the top load of pebbles 5 to 7 in. below the axis of rotation. It is also quickly put in and removed, keeps its place, and wears well. It is being introduced in this country by F. C. Brown, and seems to be giving satisfaction.

All the lime required to neutralize the acidity of ore and keep up the protective alkalinity in the agitator is introduced into the classifier. This, so far, has been about 7 lb. per ton. Overflow slime from classifier is pumped by a 4 by 18-in. Byron Jackson centrifugal pump to a 10 by 20-ft. Dorr thickener, settler, and dewaterer. A 5-hp. motor drives the classifier, pump, and thickener. The overflow solution from the thickener flows to the gold-solution tank. Should it not be high enough in gold content it can be diverted either to the weak-solution tank or the barren-solution sump-tank under the zinc-boxes. The thickened pulp flows by gravity to one of two tanks 16 by 20 ft., fitted with the Trent agitator. At this point enough KCN is introduced to bring the strength of the solution up to about 2 lb. per ton. Some of the ores, notably the White Cap, settle rather badly, but an attempt is made to keep the specific gravity of the slime in agitators at about 1.2. Of this slime, 65 to 70% will pass 200 mesh. The slime solution in each tank is kept in circulation by a Campbell & Kelly centrifugal pump run by a 5-hp. motor. The usual period of agitation in each tank is 16 to 24 hours.

The Trent agitator is well known, but as it seems to be very effective and dispenses with the installation and operating costs of compressed air required in the Pachuca tank system, a brief mention will be made. The slime is drawn from the top of the tank and forced by the pump through a central pipe at the bottom. This central pipe has four pipes radiating from it, each fitted with jet-pipes directed toward the bottom of the tank. The reaction of the discharging slime through these nozzles causes the arms to revolve at sufficient speed to give good agitation. Air is admitted into the suction of the pump and is forced through the slime charge, giving a well-disseminated aeration. Air is automatically trapped beneath an inverted hemispherical covering which surrounds the step-bearing, so that no solid or liquid matter can reach the bearing, making the friction not greater than if it were in the open air and not submerged.

From each agitating-tank, when agitation is completed, the slime is pumped to an 18 by 26-ft. pulp-storage tank, also fitted with a Trent agitator, by which agitation is continued to preserve homogeneity. From this tank the slime goes to a Butters filter-box, immediately below, which contains 45 leaves, 5 by 10 ft., with two hopper bottoms, and with the usual acid-treatment vat at one end. The slime enters the box through a large pipe, fitted with nozzles, which shoot the slime some distance out over the top of the frames. Adjacent to and on same level as the filter-box floor are two tanks, 10 by 16 ft., one containing weak solution and the other wash water. The cycle of operations is about the same as usual. One wash with weak solution and one with water are given when the vacuum is on, all except part of the water wash going to the gold-solution tank. In practice in this mill the cycle from commencing to load to the final discharge of the cake is longer than usual. With a ¾-in. cake the filter handles about 12 tons of dry slime at each cycle. The handles and levers of all the valves are conveniently arranged on the filter-floor, and all those for diverting slime, weak solution, and wash water in the desired direction are placed compactly in small space at one corner of the filter-box.

From the gold tank the gold solution goes to two steel zinc-boxes, each with 7 compartments, 3 ft. square and 30 in. deep, having hopper bottoms covered with screens to retain short zinc. The two head compartments in each box are filled with excelsior for clarifying purposes. These boxes are placed immediately above a large sump-tank, into which the barren solution falls. Adjacent to this tank and on the lowest floor of the mill are a Goulds 4-in. wet-vacuum pump, 40 r.p.m., and a Meese & Gottfried Butters 6-in. centrifugal slime and solution pump.

The mill has an addition at the lowest level containing a boiler for steam-heating the mill and solutions when necessary. It also contains an Ostermoor pipe-cutting and threading machine, and other tools. One end of this addition is partitioned off and fitted with cement floor for clean-up, drying, and bullion room. All short motor belts in the mill are of the metal link-belt pattern. The frame of the mill building is anchored to concrete block foundations extending into bedrock; the sides and roof are covered with galvanized corrugated iron. The absence of vibrations about battery and in all parts of the mill is especially noticeable. The capacity of the mill is 50 to 60 tons per day; nearer the latter figure on present ores. The capacity of lower part of mill for almost every class of ore is considerably greater than that of the upper, unless agitating and filtering operations are unduly prolonged, thus giving considerable elasticity to the treatment of different kinds of ores.

CALIFORNIA'S sea exports of petroleum and refined products for June were 20,150,449 gallons, valued at \$617,150. Crude and residuum were 297,962 barrels, valued at \$218,751. The importations were 896,000 gallons of benzine from Peru, valued at \$58,401. The production amounted to 7,327,830 bbl., and the total amount in storage June 30 was 44,919,262 barrels.

# Sketch of the Geology of Ecuador

By W. A. WOLF

\*The Eastern range of the Ecuadorian Andes includes representatives of the most ancient known rocks, the Coast on the west the most modern sedimentary formation, and the inter-Andean country with the Western range, a combination of plutonia and volcanic rock. Of the latter the first predominates in the Southern, the second in the Northern half. While neither zone excludes altogether the formations of the others, the general divisions listed below are easily recognized as is shown by the accompanying map.

1. Gneiss and crystalline schists—(Archean).
2. Cretaceous formations—(Mesozoic).
3. Tertiary formations—(Cenozoic).
4. Quaternary or 'diluvial'—(Psychozoic).
5. Alluvial or modern—(Psychozoic).

With the sediments and between them are volcanic and plutonic rocks, the relative ages of which are determined from the sedimentary formations with which they are found in relation. In Ecuador three large groups may be distinguished:

1. Granites and syenites found connected with the gneiss and crystalline schists.
2. Greenstones and porphyritic rocks found in connection with the Cretaceous formations and for the greater part of Mesozoic origin.
3. Volcanic rocks, which are characteristic of the Quaternary and recent beds, although some seem to date from the Tertiary period.

*Gneiss and Crystalline Schists.*—In general the Ecuadorian Andes consists of 'Laurentian' rocks, including gneiss, schist, and slate of a crystalline texture. The petrographical character of these rocks has been changed by chemical metamorphism since their original formation. The main elevation of the Ecuadorian Andes is relatively modern, later than the Cretaceous and probably occurred in the Tertiary period. The principal framework of the Andes has been subjected to changes from Archean times to the present day, causing many alterations, both chemical and structural. The main agency of change has been the eruptive rocks, which thrust themselves through the strata. The later rocks of aqueous origin overlie them so that their area of outcrop is limited. The surface exposure of the gneiss and crystalline schists extend through all of the Eastern range with its Eastern slopes from the Peruvian to the Colombian boundary. In the province of Loja gneiss and schist are prominently developed and descend by the Western slopes to the deep inter-Andean valleys.

*Granites and Syenites.*—True granite is found in but few places. It is sometimes found intercalated with gneiss and micaceous schist, but in these cases it is frequently difficult to distinguish from a gneiss badly developed. Syenite is found more frequently than granite but under similar circumstances, and never is extensive. Like the granite found with the gneiss, the syenite is in close relation with the amphibole schists, this relation without doubt being genetic. Mica characterizes the granite and the gneiss, as hornblende marks the syenite and the hornblende schists. Diorite in the province of Loja is found as dikes in the granite and syenite.

*Cretaceous Formations.*—The geological scale is not fully represented in Ecuador, the Paleozoic and the first two periods of the Mesozoic being wanting. No trace has been found of any formations of these periods. Wherever contacts of Archean rocks with others have been found, formations of Cretaceous or younger age rest upon the Archean. In Colombia and Peru Jurassic and even older rocks are found, and it is possible that they may be yet discovered in the deeper synclines covered with later strata or in some

region not yet studied. According to deep artesian well borings, the Cretaceous formation of the coast near Guayaquil appear to rest directly on the crystalline schists and granites. The boundaries of the Cretaceous are ill-defined as it is hard to determine the age of certain strata. Fossils are almost entirely wanting. In the majority of cases it is necessary to classify the rocks by analogy and by comparison with similar rocks in other countries. In the inter-Andean country the Cretaceous is not extensive, being covered in many places by volcanic material. In the Western cordillera it is highly developed. The beds of the Cretaceous are irregular and have been uplifted and folded. They are not found in their original position. The dip is mainly toward the West, and the strike is that of the cordillera.

*Greenstones and Porphyritic Rocks.*—These are found chiefly in the Southern provinces of the Republic. In the Northern part they are deeply hidden below volcanic rocks. Andesite, containing veins of gold quartz, is found in the Southern provinces.

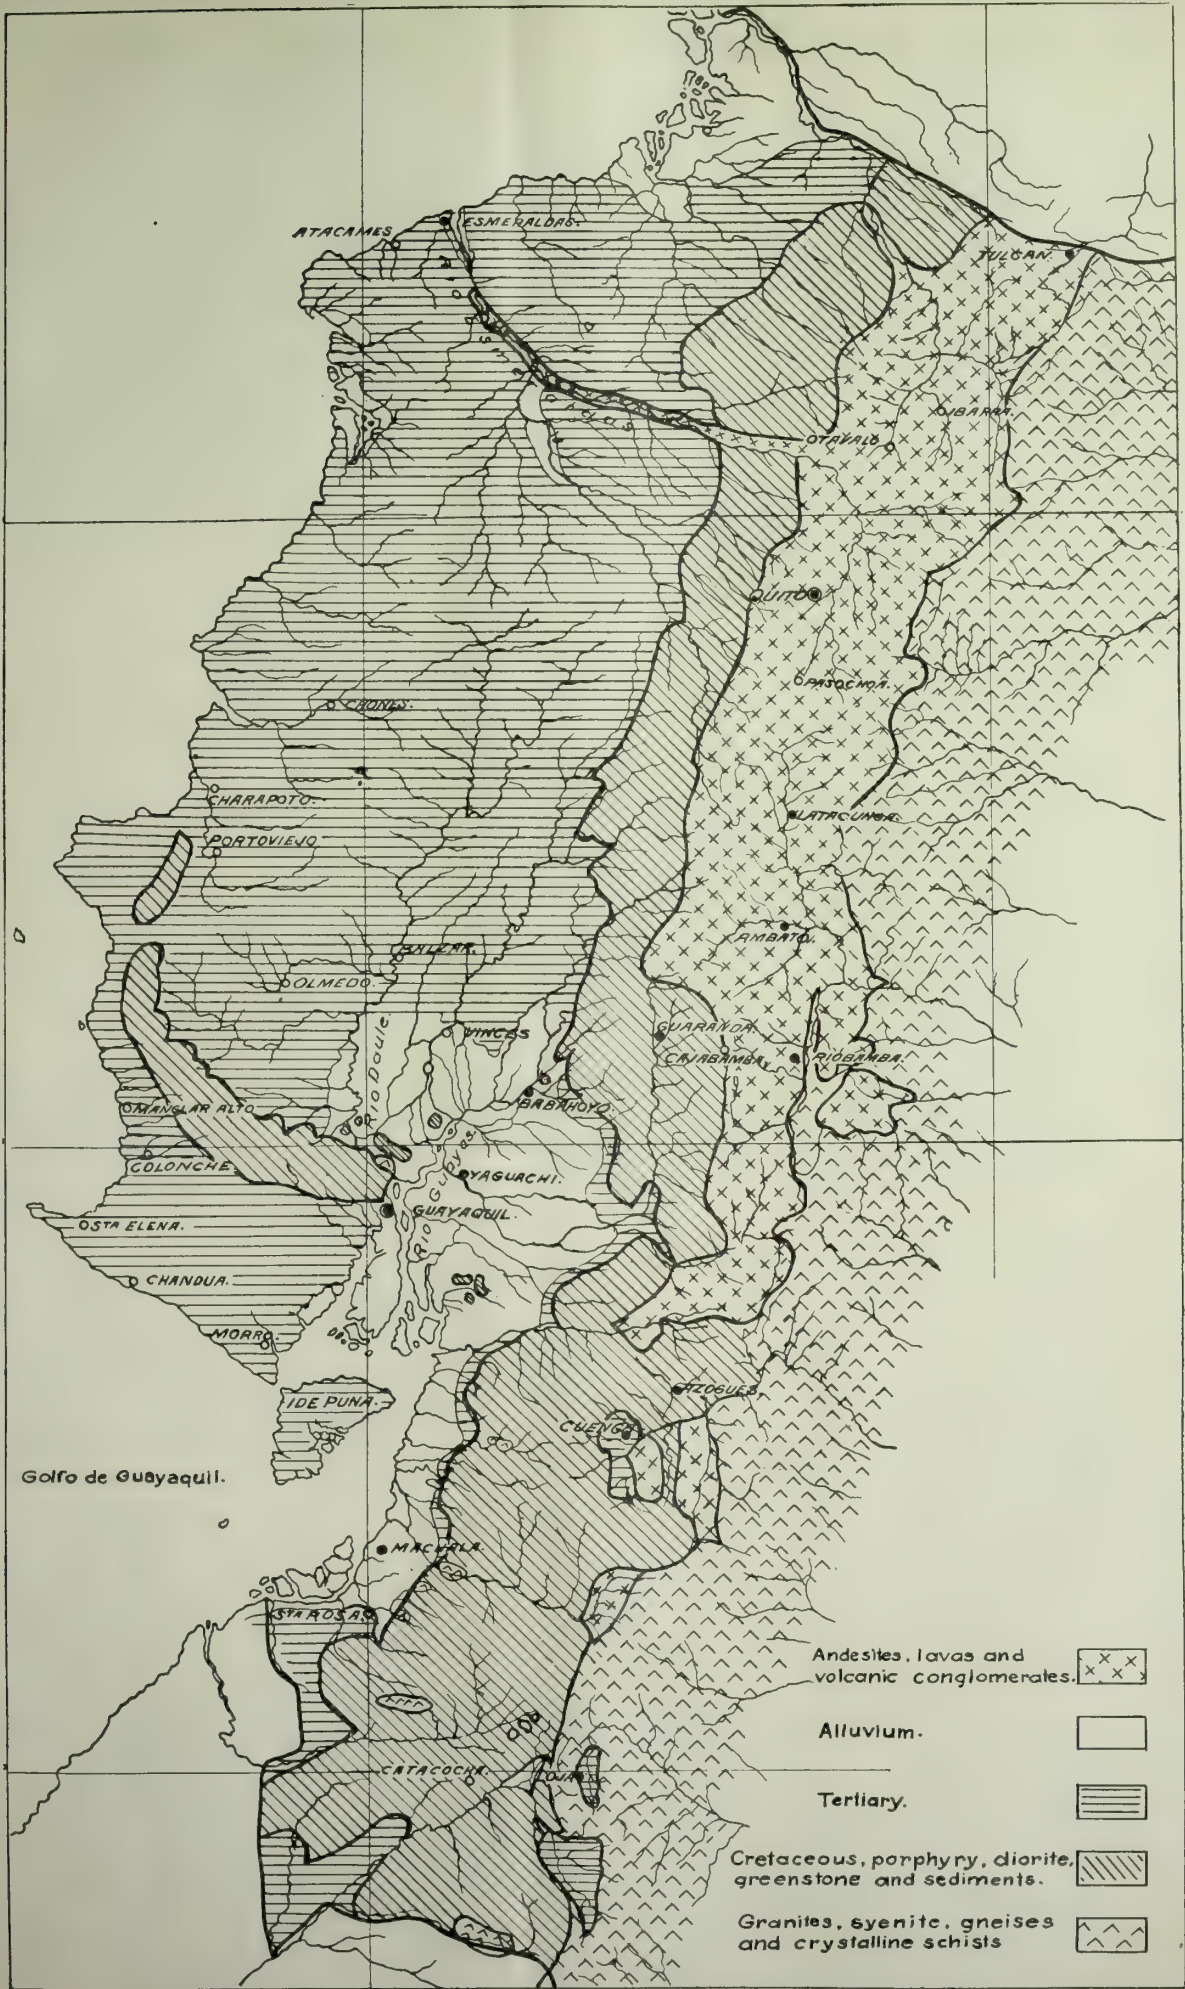

*Tertiary Formations.*—There are two distinct developments of the rocks of this period. Along the coast they consist of marine deposits, and in some depressions of the inter-Andean country they are lacustrine deposits.

*Quaternary and Modern Formations.*—Commonly the alluvial deposits are the direct continuation of the Quaternary, without notable change either in material or deposition. In these cases it would be arbitrary to fix the limits between them. It is possible, however, to distinguish marine and alluvial deposits. The marine deposits are limited to the shore belt and have a large superficial extension. The alluvial are found in all parts of the Republic but are local, being found in the valleys and over small plains. The common volcanic rocks are of Quaternary and modern age, and many lake and river deposits are made up of volcanic material.

*Occurrence of Gold.*—Quartz veins are found in the schist, gneiss, and slate formations, generally without associated minerals, though sometimes oxides of iron or manganese occur. No auriferous quartz is found in these formations. The relative poverty of the veins in the primitive formation and in crystalline rocks is striking. At Gualaceo, far across the Eastern range, gold-bearing quartz veins are reported. In silver the veins are as deficient as in gold. Notwithstanding the poverty of the veins the Eastern cordillera is an auriferous district because of the placers. Nearly all of the rivers have their source in the crystalline rocks. The majority of the gold-bearing streams have their source in the Eastern watershed from the Loja province to the province of Imbabura, because on that side the schists reach their highest development. On the Western side the gold washings are only in those provinces in which the schistose formations extend to the deep depressions of the Andes. They are richest in the province of Cuenca. It is not to be doubted that the gold found, originated in the schistose formations, because the streams carry it in larger quantities and larger grains while traversing them and as soon as they enter other formations, the gold content diminishes and the grains are smaller until it altogether disappears. The tributaries of the Napo, Santiago, and other great rivers are gold-bearing in their upper courses and barren below. In the streams of the province of Azuay gold has been deposited at a distance from the upper courses but within the schistose formations, and for this reason neither the Gualaceo or Paute river contains gold to repay washing. Gold is disseminated through the crystalline schists and which furnished the gold of the placers. Auriferous quartz veins are found in the andesite in the Southern part of the Republic.

SKETCH MAP OF GEOLOGY OF ECUADOR (AFTER TEDORE WOLF).

## The Rand Mines, Limited

JOHANNESBURG CORRESPONDENCE

During early June most of the adjourned annual company meetings were held and, seeing that the year 1911 was scarcely a satisfactory one as far as shareholders were concerned, some interesting explanations were looked for. The statement of the managing director of the Crown Mines as to why results there did not come up to expectations has already been published, and, with the exception of the great excess of capital expenditure over the engineer's estimates, may be considered as on the whole satisfactory. Perhaps the most interesting meeting was that of the Rand Mines, Ltd., where the chairman gave the usual review of the disappointments and successes of the past year. The Rand Mines-Eckstein group controls or holds shares in nearly every concern of any value throughout the whole extent of the Rand, so that its experience applies more or less to the whole Rand gold-mining industry. Its interests cover some of the best outcrop mines and, with one or two exceptions, the whole of the deep-level mines of any pronounced value. Being admittedly the most progressive group on the Rand, the review of its doings is always interesting.

At the Rand Mines meeting the chairman stated that during the year more deep-level areas had been acquired beyond the Grahamstown dike to the dip of the Robinson Deep. As this is in the richest portion of the Central Rand, and in a neighboring concern belonging to the Rand Mines the lower levels are showing improved content, the action does not throw much light on the interesting question as to whether the Rand blanket reefs become generally impoverished in depth, nor does it give as much encouragement as would the adoption of a policy of active development in the ground belonging to the Rand Mines Deep, to the immediate dip of the Jupiter and Simmer Deep properties.

The Rose Deep, Village Deep, and the Modderfontein properties all did well during the year, but at the Ferreira Deep, City Deep, and Geldenhuis Deep the results did not by any means come up to expectations. It was explained that at the Ferreira Deep the profits had been decreased, owing to the operations being handicapped during the past two years by the "great pressure exerted by the overlying strata." Now this great pressure at the Ferreira Deep would have not been so noticeable had mining operations been conducted in a proper manner; in fact, it would have not been noticed at all, as the depth at the Ferreira Deep where the troubles occurred is only about 2000 ft. However, it has been found necessary to flush over half a million tons of sand into the stopes, at a cost approaching a shilling per ton, and the process is not yet completed. The sand filling cost does not equal the losses incurred by damages to property and shafts, not to mention loss of profits, but the filling has saved the mine, and it would seem probable that in a comparatively short time, and with a better system of mining, all troubles due to subsidence should be over. At the Geldenhuis Deep, also controlled by the Rand Mines, Ltd., a similar experience was had, and sand-filling to protect the shafts and railway had to be resorted to, but in this case the position has been aggravated by decreasing content and increasing costs, necessitating a change in the management, as in the Ferreira Deep, with the object of obtaining better and more economical mining.

The chairman was careful to announce, in regard to the East Rand Proprietary Mines, in which during the year the Rand Mines, Ltd., acquired an important interest, that the Rand Mines does not control, but he considered "the present management good, and so long as the development values continue favorable as they have done hitherto, there is every reason to expect good results, while, further, there was no doubt that the backward swing of the pendulum went too far." That was a satisfactory assurance, so

far as it went, but the stockholders appear to require far more reassuring statements about the management and development prospects before they put up prices to their old level. Although the Rand Mines, Ltd., does not control the East Rand Proprietary property, it is to some extent responsible for the present management, and stockholders will want to know why the gold recovered at the East Rand Proprietary Mines has lately been a full pennyweight in excess of the average assay value of the ore reserves. At the Village Deep, an important mine controlled by the Rand Mines, Ltd., the manager has been instructed to keep the grade of ore mined at the average value of the ore reserves, and stockholders cannot understand the need of a different policy at the East Rand. If the present East Rand management is good, why should a check be placed on a similar practice to a much smaller extent at the Village Deep mine? The stockholders also want to know something more definite about the development values. In the annual report of the superintending engineer, only about a third of the total ore standing developed in the mines was shown to be profitable, and apparently the deeper sections of the property were developing in a manner not altogether satisfactory. It was the appearance of this report that made the "pendulum swing back" so far. Some of the stockholders in the East Rand are not so certain that the management is as good as represented at the meeting of the Rand Mines, Ltd. The report of the superintending engineer for 1911 indicated an ore reserve of 6,716,605 tons of an average value of 6.9 dwt. and intimated that the aim would be to eliminate, as far as possible, from mining operations, all ore of an unprofitable grade and to mill such ore as would approximate the value of the ore reserve. The former policy appears to have been carried out with a vengeance during the last few months, but the intention to mill ore of the average value of the ore reserve has been entirely overlooked in the scramble for profits. These are some of the points the stockholders of the East Rand Proprietary Mines would have been glad to have explained by the chairman of the Rand Mines, Ltd.

As to the power troubles experienced on the Rand during the past year, the chairman announced that an ample supply of electric power was anticipated in September, but that it will be from 12 to 18 months before the full supply of compressed air would be furnished. As a compromise and recompense for past losses, the Rand Mines, Ltd., has accepted £33,000 from the Power company. The chairman pointed out that a number of improvements had been effected during the year in the metallurgical practice at the mines, among them being more efficient tube-milling, classification, and the adoption of the Butters filters. The Rand Mines has in operation Butters filters capable of handling 85,000 tons of slime per month, at a cost ranging, according to tonnage and conditions, from 2.6d. to 4d. per ton, while the total extraction at the New Modderfontein and Robinson mines has been brought up to 97 per cent.

In concluding, the chairman dealt with the future of the leading properties belonging to the Rand Mines, Ltd., but did not touch in detail on the future of the Rand. The Rand Mines, Ltd., holds an 8-mile stretch of the best deep-level country in the Central Rand, and the lives of the deep mines in this area are not determined by the present dip boundaries of the existing properties. Probably no new company will be formed to incur the enormous capital expenditure and the risks that would have to be incurred in sinking to vertical depths of 7000 ft. or more. So long as the veins continue profitable in this central and richest portion of the Witwatersrand, they would be followed in depth by the existing deep-level mines. At the Village Deep mine the grade of the ore between 3500 and 4000 ft. vertical was better on the whole than that in the same mine between 2000 and 3000 ft., while at the City Deep excellent ore is found at vertical depths varying from 2400 to 3350 ft. No limit can yet be determined regarding the life of the Witwatersrand.

## Manganese Deposits of the Caucasus

By FREDERIC W. CAULDWELL

\*The manganese deposits of the Caucasus are among the richest in the world. The principal mines are situated at Tchiatouri, in the Government of Kotais, about 190 versts (126 miles) from the Black Sea ports of Batum and Poti. The exploitation of the Tchiatouri mines began in 1878, but remained on a very limited scale until 1885, when the Trans-Caucasian railway was constructed.

The ore is shipped to England, Germany, the United States, France, and Belgium, and in smaller quantities to other countries. England, Germany, and the United States are the best customers. The total export of the ore from Batum and Poti during 1908 and 1911 was:

	1908 (tons).	1911 (tons).
Poti .....	366,600	442,460
Batum .....	8,160	129,233
Total .....	374,760	571,693

The increase of the shipments from Batum during 1911 is attributed to the heavier cost of loading ore at Poti, owing to the levying, in 1910, of a duty of one-half kopek per pood (0.2575c. per 36.112 lb.) on ore exported from that port. Manganese shippers at Batum loaded several steamers with full cargoes during the first two months of the current year, and there is every reason to assume that the exports from Batum in 1912 will equal, if not surpass, those of 1911. About 15 or 20% of the manganese exported is washed ore.

Manganese ore declared for export to the United States through the consulate at Batum amounted in 1910 to 28,490 tons, of a value of \$259,898. In 1911 the export amounted to 19,685 tons, with a declared value of \$197,737. These figures represent but a part of the ore from the Caucasus that was imported into the United States. Much of the ore sent to European countries is eventually trans-shipped and finds its way to the United States. Three full shiploads are sent, on an average, each year direct from Batum and Poti to the United States in chartered vessels. The ore exported through the ports of Batum and Poti generally contains 48 to 52% of metallic manganese (Mn), while concentrate obtained from washing the granular ore and used for chemical purposes (glass-making) is shipped containing 81 to 90% of manganese dioxide (MnO<sub>2</sub>).

The mines at Tchiatouri lie in a region of horizontal sedimentary formations, divided into two principal parts by the Kvirili river. These are again crossed by numerous branches of the river, and the whole region is thus divided into seven plateaus: on the right side of the Kvirili river, Rgani, Sedergani, Mguemevi, Darkveti; on the left side, Perevissi, Chouerouti, Itkhrvisi. The total area covered by these mines is about 126 square versts (about 55 square miles), of which 100 square versts (44 square miles) contain good ore.

The outcrops of the ore are about 1000 ft. higher than the Kvirili river. The ore lies in a horizontal bed between limestone below and sandstone above. Besides solid benches the ore also occurs in granules (oolitic form) mixed with sandstone. The richest ore has been found in the plateaus of Mguemevi, Sedergani, and Chouerouti; Rgani plateau yields rich concentrating ore. According to calculations of Russian geologists, the Tchiatouri mines contain about 1,070,000,000 tons of ore, estimated to be sufficient to supply Europe and the United States for at least half a century, especially as the Tchiatouri ore is of high quality. As already mentioned, the ore lies in horizontal layers, and consequently the mines can be worked easily and at the same time over great areas by means of tunnels (galleries) and by using picks and shovels.

The mines are owned by a large number of Georgian peasants, who are without capital or knowledge of mining. Until recently, with few exceptions, the mines have been worked in a most primitive way, and as a result only about two-thirds of the ore has been recovered. Within the last six years various foreign firms have bought up some of the larger plots and have started mining by more modern methods. The lump ore is separated by hand from the sandstone; only the ore occurring in granules is concentrated in washing plants. In washing, the granular ore can be concentrated up to 60% of metal or 90% of peroxide of manganese (MnO<sub>2</sub>), but these percentages are above the average for the district.

The ore is transported to the railroad at Tchiatouri in two-wheeled ox-carts or by pack-horses, and over bad roads, for distances varying from 2 to 5 versts (1.324 to 3.31 miles), at a cost of 2 to 3 kopeks per pood (1.03 to 1.545c. per 36.112 lb.). The position of the mines is favorable for mechanical transportation of ore, especially by wire ropeways, but on account of lack of capital such methods have begun to be employed only lately and as yet are used by but a few firms.

From Tchiatouri the ore is carried on the Tchiatouri railway, a 25-mile narrow-gauge branch of the main line, to Sharopan. At Sharopan it is transferred into the cars of the Trans-Caucasian railway and shipped to either Batum or Poti. The freight rate from Tchiatouri to these ports is 70.23 rubles (\$36.17) per car of 750 poods (about 12.1 long tons) of ore, which is 9.37 kopeks per pood (4.826c. per 36.112 lb.). This rate includes all expenses of trans-shipment at Sharopan and three-fourths kopek to the Manganese Producers' Association. The greater part of this freight rate is for the distance from Tchiatouri to Sharopan, namely, 5½ kopeks (2.8325c.) for a distance of 38 versts (25 miles). The remainder of the freight rate, amounting to 3.87 kopeks, is paid for the distance of 162 versts (107 miles) from Sharopan to Batum or Poti. The best business in manganese would therefore seem to be done by the Tchiatouri branch of the state railway. The cost of building this short line was 1,500,000 rubles (\$772,500).

As most of the mine-owners are Georgian peasants with little capital, the trade in the ore has been principally in the hands of commissionaires working with the assistance of banks, which charge 8 to 9% interest. Of late considerable German capital has been invested in the mines, and much of the unworked land is now in the hands of foreign capitalists. A very important part of the manganese business for the exporter is to have at his disposal a number of well situated platforms at Tchiatouri, connected with a siding of the railroad, where stock for shipment can be stored. The Tchiatouri railroad can furnish 400 cars per day at the utmost, and these are divided among the proprietors of platforms at a ratio of 1 car for every 20,000 poods of ore kept in stock. Therefore, the greater the quantity of ore in stock the larger is the number of cars allotted to the shipper. At times of heavy shipments from Tchiatouri these rules are strictly followed by the railroad, while in slack times owners of small stocks can obtain as many cars as are free.

The advantage of keeping heavy stocks and having good platforms at Tchiatouri are: (1) The owner of these stocks can always obtain a correspondingly large number of cars. (2) When he is expecting to load a steamer at Batum or Poti it is not necessary to accumulate beforehand a large stock of ore on the docks at these ports, but he can hold his shipments at Tchiatouri and forward in time to load directly on board ship from constantly arriving cars. The shipper can thus reduce expense of interest on the railway freight; and the ore being handled but once at the docks, loading on board ship is cheaper. It needs but a glance, therefore, to see that next to the possession of mines, the control at Tchiatouri of suitable platforms of great capacity is one of the most important questions with which the trade has to deal.

The ore is put aboard steamers at Batum and Poti by

\*From a consular report.

laborers, who carry it in small baskets holding about 4 poods (144 lb.) over wooden runways erected from the dock to the steamer. In this way, and with a sufficient number of laborers, 400 to 800 tons of ore is loaded per day. If the ore is handled direct from arriving railroad cars, the cost of loading into the hold of the steamer is  $\frac{1}{2}$  kopek (about  $\frac{1}{4}$ c.) per pood; but if the ore is loaded from the docks, upon which it has previously been discharged from railroad cars, the cost is  $\frac{3}{4}$  kopek. About six years ago there was constructed at Poti an elaborate elevator for loading the ore on board ship mechanically, but up to the present time this elevator has not come into general use. To pay for this improvement a charge of  $\frac{1}{2}$  kopek per pood has been recently placed by Poti on all ore going from that port. The result has been to divert shipments to Batum.

The Manganese Producers' Association, of which mention has been made, levies a tax of  $\frac{3}{4}$  kopek per pood on all ore sent by rail from Tebiatouri. It is given the right by the Government to levy up to 2 kopeks per pood. The income derived from this tax is set apart for bettering conditions about the mines. The managing council of the association is elected at an annual meeting of manganese producers and exporters, at which apparently the voting regulations are such as to give the small dealers an overwhelming majority. As capital becomes more and more necessary to carry on deeper mining, the tendency is for the small producers to disappear, but they are still sufficiently numerous to be able to elect a council in sympathy with their views, and are urging the council to expend the proceeds of the tax to assist them to compete with the larger capitalists. They point out that some of the larger capitalists, having installed mechanical transportation of ore from the mines to the railway platforms, have an advantage over those who are still obliged to use bullock carts. The small producers are urging the council to expend 1,000,000 rubles (\$515,000) for mechanical means of transport which shall be at the disposal of all producers.

The council has also under consideration new plans for the supply of water to the mines, for housing workmen, and other improvements which are to be carried on from the funds procured from the tax. Altering the present branch line between Sharopan and Tebiatouri to a broad gauge has been under recent consideration by the state railway engineers. Such improvement would eliminate the necessity for transshipping the ore from the trucks of the narrow-gauge line to the trucks of the main line at Sharopan. Exporters are urging a reduction of the railway rates that will bring the rate on the Tebiatouri branch line down to something like the normal rate for such service.

A feature of the manganese industry during 1911 was the marked increase in the quantity of ore washed at and about the mines, to the great discomfort of the population using the waters of the Kvirili river for domestic purposes. Most of the washing plants have been erected on the banks of the Kvirili or its tributaries, and the tailing from these plants has polluted its waters to such an extent that complaint was made to the viceroy. The Manganese Producers' Association has devised a plan which seems likely to meet the exigencies of the case. It is proposed to construct a large dam in the valley of the Kvirili river below Tebiatouri, at which slime from the washing plant will be arrested. The water would there be purified and the overflow from the dam would be utilized for generating the electric current required for lighting the village of Tebiatouri, for electrifying the Sharopan-Tebiatouri branch railway, and for converting manganese waste sediment into ferromanganese in electric furnaces. It is estimated that the washing plants now in course of construction, when completed, will have a daily capacity of about 2613 tons of ore averaging approximately 53% metallic manganese in the dry state and make 1460 tons of tailing containing 30% mineral to waste in washing the first-named quantity of ore.

## Alumina in Slags

By H. C. BELLINGER

\*During the past two years a number of highly interesting articles on the action of alumina in slags have appeared in the technical journals. These have been written by well known metallurgists, who have advanced theories and drawn conclusions of a definite character, which undoubtedly have faithfully represented the action of alumina under the different circumstances attending the smelting operations leading to their convictions. Having had a somewhat varied experience in the treatment of ores containing alumina, I feel that some of the conclusions arrived at are apt to be to a great extent misleading.

It will be interesting here to quote the opinions of various authors and metallurgists on the action of alumina. A great diversity of opinion exists among our chief metallurgists, and the reason for this, after all, is easily understood when we consider the erratic action of this element. We will take as a first example the ores from the Rossland district, British Columbia. With reference to the orebodies, I can best quote from J. F. Kemp, who states as follows: "The orebodies exist at or near the contact of gabbro and porphyry, the extent of the mineralized zone being about four miles long by one mile wide. The contact is not abrupt, but the gabbro passes gradually into augite, porphyrites, and diabases, seldom more than one mile wide and brecciated." The gangue matter analyzed approximately as follows:  $\text{Al}_2\text{O}_3$ , 14 to 18%;  $\text{CaO}$ , 10 to 12%;  $\text{K}_2\text{O}, \text{Na}_2\text{O}$ , 2 to 3%;  $\text{SiO}_2$ , 40 to 46 per cent.

The first metallurgist who attempted to smelt these ores arrived at the conclusion that the alumina should be calculated as an acid, and found on this assumption that a certain percentage of limestone was required. The furnace was blown in, but the campaign abruptly terminated at the end of two hours by the freezing up of the furnace. The metallurgist concluded that the alumina was more active than he had first considered, and therefore increased the percentage of limestone, with the same disastrous results. The company then decided to call in another metallurgist, who took an entirely different view of the alumina. He assumed that the part of the alumina which was in combination with silica would continue to perform the function of a base, while the remainder would probably assume the opposite rôle, which happened in this case to be equivalent to eliminating the alumina entirely from the calculation. A change was made upon this assumption, and no difficulty whatever was experienced, the result being in every way highly satisfactory. No practical alteration was made in the composition of the charge for some years, the regularity of the ore making this unnecessary. While in this particular instance the alumina appears to have played no prominent part in the formation of the slag, at the smelters at Butte, Montana, where the economic conditions demand the formation of a slag ranging from 45 to 50%  $\text{SiO}_2$ , the alumina definitely assumed the rôle of a base, as the following analysis will testify:

	Per cent.		Per cent.
$\text{SiO}_2$ .....	45.4	$\text{CaO}$ .....	18.5
$\text{FeO}$ .....	24.0	$\text{Al}_2\text{O}_3$ .....	7.9

It will be seen that here 24.2 oxygen units are contained in the acid, while the base units give 10.62 units of oxygen, the result being a true bi-silicate slag. If the alumina be included on the acid side, the ratio is 2.6 to 1. A similar substance is shown in the Northport slags of the following composition:

	Per cent.		Per cent.
$\text{SiO}_2$ .....	43.5	$\text{MgO}$ .....	4.5
$\text{FeO}$ .....	20.0	$\text{Al}_2\text{O}_3$ .....	14.5
$\text{CaO}$ .....	16.0		

\*Excerpt from an address before the Australasian Institute of Mining Engineers.

Here there are 23.3 units of oxygen in the silica and 10.81 base units in the FeO, CaO, and MgO, while 6.75 units are included in the alumina. If the latter be taken as acid, the acid ratio is 2.8 to 1. The following slag represents a two-weeks run at the Britannia plant, Vancouver island:

	Per cent.		Per cent.
SiO <sub>2</sub> .....	50.4	CaO .....	22.22
FeO .....	20.5	Al <sub>2</sub> O <sub>3</sub> .....	6.5

Here there are 26.88 acid units of oxygen in the slag, and only 10.7 in the base. Including the alumina as a base, the oxygen ratio approximates the bi-silicate, while including it as an acid the ratio would be 3 to 1, which is beyond reason.

Again, at Croftin, British Columbia, I was engaged in the smelting of ore containing barite with an average of 40 to 50% barium sulphate. These ores also contained from 8 to 9% zinc. On account of the low formation point of the slag resulting from this ore, it was necessary to add both silica and alumina before the furnaces could be made to run satisfactorily. The slags ranged from 5 to 12.2% alumina, and the action of alumina here was most confusing. The aim at this, as well as at other plants, was to utilize, so far as possible, the base units, and the object, therefore, was to crowd as much silica upon the charge as possible. All of the slags resulting from the various mixtures made were commercial, and ran in a highly satisfactory manner. Still I found that in some cases the alumina apparently acted as an acid, while in the other cases similar assumption would clearly have resulted in an impossible slag, since the result would have been a ratio of 2.7 of acid to 1 of base. Neglecting the alumina, the ratio is 1.91 to 1, closely approximating a bi-silicate type.

Then, again, at Cobar there are anomalies, as the following figures will testify:

NEUTRAL ALUMINA (PER CENT)

Cu	FeO	SiO <sub>2</sub>	Al <sub>2</sub> O <sub>3</sub>	CaO
0.2	49.2	41.4	5.8	1.0
	2	5 1/3	46.6	2
<hr/>				
9/98.4				
	10.93	2070	348	
	28	138	232	7/2.0
<hr/>				
	11.21		2.7028	0.28
	2 22.08			
<hr/>				
	11.04			

ACID ALUMINA (PER CENT)

Cu	FeO	SiO <sub>2</sub>	Al <sub>2</sub> O <sub>3</sub>	CaO
0.3	51.4	39.2	6.5	0.6
	2	5 1/3	466	0.2
<hr/>				
9/1028		1960	390	7/12
<hr/>				
	11.42	130	390	0.17
	0.17		260	
<hr/>				
	11.59	3.02	3.0290	
<hr/>				
	2/23.92			
<hr/>				
	11.96			

In the cases above enumerated the alumina acted in various ways—acid, base, and neutral.

From the foregoing figures and extracts it is obvious that the function of alumina still remains in a decidedly unsatisfactory state of uncertainty. I have operated plants where the slags seem to have placed beyond all doubt the definite action of alumina in one or other of the various allocated rôles. But from diversified experience it is plain that it is necessary to look beyond the mere chemical an-

alysis of the ore in order to evolve a reasonable and definite process of action for alumina. Take, for instance, the porphyries with the large influence of the feldspars in evidence, and certain combinations exist for the silicates of alumina and other bases. The feldspars constitute an extensive list of minerals with a wide range of composition, from orthoclase with 18.4% Al<sub>2</sub>O<sub>3</sub> and 16.9% K<sub>2</sub>O, to anorthite with 36.7% Al<sub>2</sub>O<sub>3</sub> and 20.1% CaO. Both these feldspars, physically and chemically, in their behavior under similar treatment, are widely divergent. Thus on through the various metasilicates and orthosilicates to the hydrosilicates, conditions vary physically and chemically with widely different genetic laws. The range of oxygen ratios varies from less than one to one in the subsilicates to four to one in the disilicates. Considering the many conditions of combination in aluminous compounds, and noting the definite changes in the action of the alumina in sympathy with variations in such combinations, it becomes quite possible that under similar furnace conditions the compounds may be reasonably expected to adopt rôles suited to their peculiar forms. Many engineers have, for instance, found under certain conditions that by calculating the alumina soluble in acids on the acid side, and treating the insoluble alumina either as base or as an independent elementary magma, they have attained excellent results. Though Peters says that this method has no scientific foundation, it is interesting to note that it has been a success in some cases, and the reason for this success may in the future be reduced to a scientific basis. At Cobar a series of experiments is being made. While the outcome of these may not alter the present status of alumina, it is hoped that the information secured will be of some value.

## Gold and Tin Production of Seward Peninsula

The gold produced in Seward Peninsula, Alaska, for 1911 had a value of \$3,100,000, which was a decrease of about \$400,000 compared with the figures for 1910. This falling off, according to P. S. Smith, of the U. S. Geological Survey, is attributable to three main causes—first, a decrease in the amount of winter mining; second, a general decrease in mining operations, except dredging; and third, the handling of low-grade material. All these causes may be referred more or less directly to the exhaustion of the known rich bonanzas before enterprises have been established capable of handling cheaply the large amounts of low-grade material which are known to exist in the peninsula. From this statement it may be inferred that at some future time the gold production of the Seward Peninsula will materially increase.

Although practically all the mineral production has been derived from gold placers, interest has been renewed in the tin deposits, and a production of nearly 100 tons of concentrate, worth about \$50,000, is reported from the tin placers on Buck creek. Not only has dredging for placer tin been carried on, but certain lode tin mines near York have been reopened under the superintendence of a competent mining engineer. It is understood that the company intends to ship the tin concentrate to Seattle, where it will be smelted.

## The Silver Market

'Samuel Montagu & Co. reports that the market has become unsettled, not, however, before prices broke recent records. On June 22 the quotation for cash touched 28 9/16d., the highest for that delivery since October 12, 1907, while that for two months, 28 11/16d., on the same day, was the highest for forward delivery since October 23, 1907. These prices were maintained on June 23, but since then quotations crumbled 1/8d. per day until June 29, when a small reaction of 1/16d. occurred.

## Electrical Factor of Safety

The United States Bureau of Mines has issued Technical Paper No. 19, written by H. H. Clark, on 'The Factor of Safety in Mine Electrical Installation.' The paper calls attention to the fact that wherever the service conditions are indeterminate or variable, engineers are accustomed to use factors of safety in their designs, especially in those cases where the protection of human life is a consideration. The author believes that a similar factor of safety should be used in connection with the electrical equipment of mines. To quote from the paper: "The safety of operation of electrical mining equipment is an engineering problem that involves the element of human life and that is influenced by conditions and events that cannot always be foreseen. The successful solution of the problem will, therefore, depend largely upon the factor of safety that is considered in the selection, installation, and maintenance of such equipment." Mr. Clark classifies the electrical accidents that may occur in mines, and enumerates the principal sources of danger incident to the use of electricity underground. The conditions surrounding electrical equipment in mines are compared to similar conditions above ground and the requirements of mining work which present difficulties in the way of maintaining electrical apparatus in perfect conditions are noted. The effect of roof falls, dampness, dust, and acid water are mentioned. The temporary character of underground work limits the economical investment in electrical equipment and its installation. Mr. Clark does not regard the safeguarding of mine electrical equipment as a simple problem, and states that there is no general formula for its solution. It is suggested, however, that a logical first step would be to remove contributory causes by placing lights and erecting guards at particularly dangerous points, and by selecting apparatus especially designed to offset the effect of dampness and dust. He says: "The problem of safeguarding may be divested of some of its vagueness and put in concrete form by considering that if the electric current can be kept where it belongs—in the conductors designed to carry it—it cannot give shocks, set fires, or ignite gas, dust, or explosives. Electricity becomes actively dangerous only when it breaks away from its proper channels in stray currents or as sparks and arcs." The paper lays stress upon the importance of first-class installation at the outset and frequent inspection of equipment after it is in place. Mr. Clark considers that a competent electrician is needed to insure the safest and most efficient operation of mine electrical equipment, and dwells upon the responsibilities and requirements of such a position.

## Framing Shaft Sets

By TOM McCORMAC

There are three aids to fast work in framing shaft sets: an accurate set of templates, corresponding to the system of framing in use; a boring machine; and a big cross-cut saw, 7 or even 7½ ft. long.

The templates can be quickly made out of any light board, and they may be faced at each end, if desired, with galvanized iron or heavy tin. They save a lot of time in measuring, they prevent mistakes in framing, and above all, they are accurate. When it is remembered that an ordinary miner will miss, in measuring a 9-ft. distance with a square, the correct measurement by ⅜ in., even this last point has its value. Using the templates, any variation in the size of the timber is instantly seen, and the required allowance in framing is marked. This does away with 'sizing' each timber; a needless refinement.

The boring machine, which can be purchased for a few dollars, insures the holes for the hanging-rods being straight; this in turn insures the set to hang in its place when the rods are tightened, and reduces the labor in blocking the

set to its place in the shaft. It also saves its cost quickly in the reduction of labor in the boring of holes. It takes an appreciable part of the time of a shift to bore the holes in a set of timbers with a brace and ship-auger, as there seems a strange coincidence in the finding of knots just where it is necessary to bore the holes.

The big saw is, however, the greatest help. In the hands of two men who have had a little practice it does rapid and accurate work. In starting the saw it is generally advisable to use a guide, which can be either a small block lightly nailed against the mark on top of the timber, or a short piece of heavy timber placed against the mark to be sawed. Either will steady the heavy saw until the cut is started. Not only may the big saw be used to cut the timbers to the proper length, but it may also be used to make the necessary framing cuts.

After the stick of timber has been cut, squarely, to the proper length and all the framing cuts finished with the big saw, each end is finished with the adz, slick, and plane. In the frequent case of a knot occurring at the end, the rip-saw will give better results than will the adz, although in ordinary wood the adz is the faster tool to use.

There is no high degree of skill required in the framing of shaft sets if the standard methods of framing be adhered to. W. H. Storms has pointed out that the beveled corner has no place in the modern shaft, to which teaching I am in full agreement. It was designed to prevent the plates from splitting at this point under heavy pressure, and as it fails in that purpose, I can see no good reason for retaining it, particularly as it makes framing nearly doubly as expensive. The ordinary carpenter, in getting out a shaft set, will usually have it accurate and each joint a good fit; in a word, the set will almost invariably represent a finished job, except in one particular. Few timber framers make any effort to have the outside of the corners flush, and it is against these corners that the blocking will press. If the wall-plate is a quarter or half an inch wider than the length of the tenon of the end-plate, the blocking is going to be a little less solid than it would be were the corners flush. This, it is true, is not of great importance, but since the corners can be quickly finished evenly, by a little rough work with hand-axe or adz, it would seem to be advisable to have the work done.

## Goldfields of New Zealand

The annual general meeting of the Consolidated Gold Fields of New Zealand, Ltd., was held in London on June 28. The chairman of the board of directors, Sir W. B. Perceval, made the following statement. "On the whole I think shareholders have every reason to be satisfied with the result of the year's work. The reports and accounts reveal two facts. The first is that, both as regards the mine we are working ourselves, the Wealth, and the mine we have such a large interest in, the Blackwater, the developments are of a highly satisfactory character; while as regards the Progress mine, in which, again, we have a very large interest, recent developments are also more encouraging than for some time. The other fact is that large expenditure has been incurred on development and in additions to the plant at all of the mines, and, inasmuch as the money for this outlay has been found by our company, the result is that our cash resources have been correspondingly reduced. It is true that the effect on our balance-sheet is that our carry-forward of £51,599 is largely made up of loans to our subsidiary companies; but, inasmuch as these loans are absolutely good, it does not, to my mind, give ground for unfavorable comment, and by making these loans we have enabled our subsidiary companies to do necessary work on very much better terms than could have been obtained elsewhere. We hold 93,224 shares in the Blackwater company, and it is pleasing to note that this company continues to earn good profits, and, what is more pleasing still, by the favorable nature

of the developments of the mine the intrinsic value of our share-holding has considerably increased.

"With regard to the Progress mine, we have never lost faith in this mine. We have been devoting special efforts for years past to coax the Progress to reveal the position of its dislocated orebodies, and a trained geologist, H. Norton Johnson, imported for the purpose from the United States, has been at work since October 1910, resurveying the mine and studying the vagaries of the formation. Recent developments are distinctly encouraging, and there is hope that the Progress will at no distant date resume business and again enter the dividend-paying list. We have in that company 169,943 shares.

"During the year the operations at the Wealth of Nations mine have been of an exceptionally satisfactory character. The tonnage treated was 24,968, an increase of 3605 tons over the previous year, the total value of gold recovered, including concentrate, being £50,374, or an increase of £13,989; the yield per ton being 40s. 2.21d., against 34s. 7d. for the year before, an increase in value of 5s. 7d. per ton. The working expenditure was practically the same as the previous year, but the working profit came out at £27,352, or 21s. 10d. per ton, against £16,703, or 15s. 7d. per ton, the total result being an increased working profit of £10,649, equal to 6s. 3d. per ton."

## Quicksilver in the Urals

ST. PETERSBURG CORRESPONDENCE

The occurrence of cinnabar in the Urals has long been known, and in the gold sands it was quite common to find angular pieces and pebbles of cinnabar; for example, in the Bogosloff district, in the Miask gold sands, and elsewhere; and at last an original deposit of cinnabar in the Urals has been discovered. The story of the discovery is fairly interesting.

In 1904 the *staratelli* (free laborers) at the gold mines of the Verch-Isset factories on the Ayatsky estate in the district of Ekaterinburg, about 40 versts from the Neviansk factory, discovered both vein and sand gold, but of so low grade that they did not attempt to work it. In 1910 they went back to the vicinity and in the wall rock found mineral. The samples were assayed and antimony and a fair content of gold discovered. But it is expensive to separate the gold from antimony ore, and it requires special apparatus which is not at the disposal of the *staratelli*. Therefore, this deposit was once more abandoned without having been exploited.

In 1912 the Verch-Isset factory managers found that not far from the works carried out by the *staratelli* *Zbie-revy* there was found, along with the gold, a reddish ore which volatilized on exposure to fire. Samples of this substance showed a mercury content as high as 10%. Besides mercury, there was a content of gold amounting to between 2 and 6 zolotniks per 100 poods and silver to 2 zolotniks (one pood equals 36 pounds). After this Ryuniy, the mining engineer, made an investigation. In the shafts at 2 arshines depth (1 arshine equals 2 ft. 6 in.) the vein was found to be 2 vershoks wide (1 vershok equals 1¾ in.), and at 22 arshines depth its thickness increased to 3 vershoks. By a cross-cut a second vein similar to the first was discovered. The thickness of this vein was 12 vershoks. The character of the veins does not change along their length. The cinnabar in the first vein, as in the one parallel, was in lumps between the cracks, in places forming rich pockets.

Besides these two veins a series of other thinner veins with traces of gold occur. The cinnabar is in very irregular veins showing only traces in some places, but near the edges in rich pockets. A smaller pocket was found in the northeast drift, covering 12 v. wide and about 1 a. long. The second pocket is found deeper in the shaft. In these pockets all the fragments are incrustated with cinnabar and have been christened by workmen *zembyiky* because of their bright color. Perhaps a new branch of pro-

ductive industry—mercury mining—will be developed in the Urals, and it is quite possible that the discovery of the first deposit will by no means be the only one.

## Coal Mines of North China

The largest coal mines in China are those of the Chinese Engineering & Mining Co., Ltd., at Tongshan and Linsi, about 75 miles northeast of Tientsin. These mines were started under Chinese administration in 1878, but were reorganized as a British corporation in 1900. The relative rights of the Chinese and foreign interests involved have been in constant dispute since that time, but have finally been settled by an agreement, of which the following details are taken from a prospectus recently issued by the British company. In the year 1906, and with the authority of the Chinese Government, a company was formed called the Grand Mining Company of Pei-yang & Lanchow (the Lanchow Mining Co.). This company was granted extensive mining rights in the Kaiping basin, notwithstanding that exclusive mining rights in the basin were claimed by the old Chinese Engineering & Mining Co., Ltd. The Lanchow Mining Co. proceeded to open and to work certain mines, but some years elapsed before the competition thus created became effective. In the year ended February 28, 1911, the Chinese Engineering & Mining Co., Ltd., with a view to meeting the competition and to forcing a settlement of the dispute respecting the rights of the two companies, began to reduce the selling price of coal, and further reductions have been made from time to time down to a recent date. It was in consequence of this reduction of the selling prices that the profits and the dividends for that year showed a decrease. Negotiations have been proceeding for a considerable time past between the two companies and between the British Government and the Chinese Government with a view to the settlement of the differences between the two companies. An arrangement has recently been concluded which has received the approval and confirmation of the Chinese Government, contained in a communication to the British minister in Peking, dated March 18, 1912, which was acknowledged and confirmed by a despatch of the British Minister to the Chinese Government, dated March 19, 1912. These documents have been incorporated in a formal agreement, dated June 1, 1912, which has been approved by the British and Chinese governments.

Under the arrangement just concluded the business of the two companies is to be combined and worked as one business under a joint administration known as the Kailan Mining Administration. After making provision for the interest on the debenture issue, the amount required for the purpose of the sinking fund, and for a reserve for depreciation, the profits of the business up to £300,000 are divisible, 60% going to the Chinese Engineering & Mining Co., Ltd., and 40% to the Lanchow Mining Co. The profits in excess of £300,000 and the profits from any new business and shafts worked by machinery away from the present shafts are to be divided equally between the two companies. In addition to the existing mines of the two companies the Kailan Mining Administration will have control of the mining rights of the Kaiping basin, an estimated area of 100 square miles, being 20 miles long by an average of 5 miles wide.

The output and profits of the Chinese Engineering & Mining Co., Ltd., for the seven years ended February 28, 1911, were as follows:

	Output	Gross	Reserve for	Dividend
	(tons).	Profit.	Depreciation.	Rate,
			Balance.	%.
1905 ..	876,725	£189,754	£40,000	£149,754 10
1906 ..	833,679	170,230	30,000	140,230 10
1907 ..	1,000,201	236,980	40,000	196,980 15
1908 ..	1,117,570	214,436	25,000	189,436 15
1909 ..	1,226,069	234,926	40,000	194,926 15
1910 ..	1,359,501	234,448	30,000	204,448 15
1911 ..	1,170,163	182,908	35,000	147,908 10

## Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

### Words and Their Use

The Editor:

Sir—I note that in reprinting my paper on zinc-dust tests in your issue of May 11, the word "classification" was substituted for "elutriation", while a note on your editorial page intimated that the latter word was erroneously used in the original. Permit me in self-defense to point out that my use of this word, in the sense of the separation of extremely fine material by the use of water, is entirely correct, or at least that it has the authority of Murray's new Oxford dictionary of the English language in addition to the precedent established by good technical writers for a century or more. 'Elutriation' was not used under the impression that it was synonymous with the term 'classification' as used broadly, nor with its more restricted meaning of 'hydraulic classification' as applied to crushed ore, but as hydraulic classification of very fine particles.

The fact that the Century dictionary defines "elutriate" merely as "to purify by washing; to purify generally" is scarcely sufficient to set aside the continuous usage of the word in the other sense. The Oxford dictionary gives "to decant, to strain out, to purify by straining. In chemistry: to separate the lighter from the heavier particles of a pulverulent mixture by washing." Thorpe's dictionary of applied chemistry agrees with the last definition. Where I have met the word in the literature of the arts, the meaning implied has generally been the separation of extremely fine particles from others less fine, rather with a view to the saving of the finer material than the cleansing of the coarser, by means of a relatively large amount of water, which is decanted either intermittently or continuously and allowed to settle. Among the materials so treated may be mentioned clay, chalk, bone ash, and various abrasives such as flour emery. In some cases, however, the object was to correct the coarse portion, and in some the removal of soluble substances was apparently contemplated.

R. H. Richards uses the word in both his recent works on ore dressing, while another writer (A. S. Cushman, I believe) has gone so far as to apply the term "air elutriation" to describe the classification by means of an air-blast of finely powdered silicates which it was undesirable to moisten, using for that purpose one of the familiar glass soil elutriators designed for use with a current of water. Of these apparatus a number of forms are in use, of which Hilgard's is a well known example.

W. J. SHARWOOD.

Washington, D. C., June 27.

[The citations which Mr. Sharwood adduces to buttress his use of 'elutriation' may serve as well to exemplify the reasons for refraining from its use. Riemann has defined natural science as "the attempt to comprehend nature by means of exact concepts." A word which in its technical sense is so diffuse as to mean "to decant, to strain . . . to separate by washing" is not of great service in the expression of exact concepts regarding the process involved or in conveying them to the mind of another. The operation described was exactly that of hydraulic classification, in the limiting case where only one mineral substance is present, and was best described by the word classification, which conveys a fairly precise idea to the minds of metallurgical and mining engineers. The transfer of exact concepts from one mind to another offers great difficulties at best, and authors should constantly remember the reader, while the use of exact language is often a great aid in the formulation of exact concepts as well.—EDITOR.]

### Agitating Concentrate

The Editor:

Sir—At the Homestake mine at Neal, Idaho, the concentrate is slimed and treated by four to six agitations and decantings in 5 ft. 8 in. by 15-ft. Pachucas. After decanting, a great deal of trouble was met in trying to get the agitation started. The fine concentrate would settle into a cement-like mass in the cone, choke the valves, and resist all efforts to get the air up through it. Incomplete success was obtained by poking the mass with a hand agitator until it was loose enough for the air to break through, but even then the valves and central pipe were usually so clogged that good agitation would not start for hours. Vari-

DEVICE FOR AGITATING CONCENTRATE.

ous kinds of check-valves were tried on the air-inlet pipe, but none of them kept the concentrate from backing into the air-pipe when the pressure was turned off.

The difficulty was overcome in this manner: a 17-ft. piece of 1-in. pipe (A) was fitted with a perforated sleeve and a plug at one end, and lowered, plug end down, into the Pachuca through the central pipe. The upper end was connected by 8 ft. of rubber hose to the main air-pipe. This 17-ft. pipe was raised about 6 ft. and slipped over a hook in the rafters. When it was desired to start the agitation the air was turned on (valve B), the pipe was lifted from the hook and dropped. The Pachuca required no further attention until the agitation was complete.

For the first five minutes after the agitating-pipe is dropped, the agitation is confined to within the central

pipe, then the weight of the agitator carries it down into the point of the cone and the whole charge is stirred. Finally, in not more than 15 minutes, there is a gush up the centre tube and good circulation is established and maintained. When the agitation is complete the agitating-pipe is lifted, hung on the rafter hook, and the air turned off. When the concentrate settles, the lower end of the agitating-pipe is above the mass, and it is impossible to choke it up.

There is a battery of four small Pachucas equipped with these agitators, and there was not a single case of clogging in six months. This agitator works clear to the bottom of the cone, thus preventing any settling, and after the circulation up the centre is once set up, there is no tendency for the air to escape up the outside of the central pipe. This scheme might be applied to larger Pachucas by operating the agitating-pipe with a chain block.

J. E. ALLEY.

Alta, Utah, June 30.

### Life Membership in the Institute

The Editor:

Sir—In the report of the committee appointed to investigate the financial affairs of the American Institute of Mining Engineers, attention is drawn to the fact that the sums paid in for life memberships have not been reinvested to create an income to meet the expense of furnishing life members with publications. Permit me to point out that not only this feature, but the whole system of life memberships, as enforced in the Institute as well as the other national engineering societies, is totally unscientific. Until ten years ago, any member of the Institute not in arrears might become a life member upon the payment of \$100, but evidently the financial disadvantage to the Institute of such an arrangement became recognized, for the sum has been increased to \$150. Whether this will reimburse the Institute for the dues thus compounded depends entirely upon the age at which a member purchases a life membership. A member at the age of 21 (the earliest age at which he may join) should, according to the Institute of Actuaries annuity tables, pay \$185, which must be reinvested at 4% to meet the obligations incurred in accepting his life membership. The present payment of \$150 is, at 4%, only correct for an age of 40½ years; younger men pay too little and older men too much. The experience of the Institute as to the average age of the members purchasing life memberships has apparently never been made a matter of record, but it seems probable that the younger men would be the most likely to buy life memberships, as older men with any financial experience would not be slow to perceive the financial disadvantage to themselves involved. Under the present flat rate the Institute is losing money on every life membership it accepts under age 40, supposing an interest rate of 4%; or, at an interest rate of 5%, under age 29. The Equitable Life company's charge, for example, for a ten-year annuity at age 30 is \$212.90, and at age 40, \$185.20. With the present arrangement, any Institute member under 40 reaps a considerable advantage by buying a life membership from the Institute, while an elderly man would do better to buy an annuity of \$10 per year, payable to the Institute, from a life-insurance company. What advantage the Institute derives from a life membership, beyond a guarantee that the member will not drop out, I do not clearly perceive, but it is evident that the present uniform cost of life membership is unscientific and probably a source of loss to the Institute.

MEMBER.

San Francisco, July 19.

[The condition is not quite so bad as our correspondent suggests. Aside from what may be called 'overhead charges,' the actual annual expense per member is estimated by the Committee of Five at \$3.50. If, therefore, the \$100 originally charged had been invested at 4%, the extra cost involved in accepting a member would be fully

met, and, in lieu of his contribution *pro rata* to the fixed charges, the Institute would have the reversion of \$100 (now \$150) at his death. In the long run it is difficult to see how this could work to the disadvantage of the Institute, even if it is unscientific. In the short run, as at present, there might well be too large a proportion of life members, since the above scheme contemplates a sufficient number of contributing members to fully carry the 'overhead charge.' The Committee of Five has recommended that no more life members be accepted until the proportion drops to five in a hundred, and that this proportion be thereafter maintained as a maximum. It is also recommended that money derived from this source be used for the present to retire the mortgage on the land, thereby earning 7%, and later deposited as a separate trust fund.—EDITOR.]

### Gold and Soot

The Editor:

Sir—The condition of affairs in Adelaide, Melbourne, and Sydney reminded me of T. A. Rickard's article, under the above heading, in your journal some weeks ago. These cities, with populations of about 180,000, 580,000, and 600,000, respectively, are greatly interested in the production of gold and other metals, and are considered to be comparatively wealthy. As regards soot, it is high time the authorities took steps to minimize the nuisance. On leaving Adelaide by express and reaching the top of the hills behind the city at 5:20 p.m., a huge mantle of smoke is seen hanging over the place, produced by numerous factories and trains. Soot is continually dropping on one, which is undesirable. In the streets there are large numbers of motor cars, and the exhaust from these may be seen for some distance, showing, I should say, incomplete combustion of the petrol used. Coupled with the dust from street traffic, the air is not of the best quality.

In Melbourne smoke produced by factories, power plants, steamers, and trains hangs about all the time. The railway department has laid out rather pretty gardens at several stations, but flowers and shrubs have a dark appearance, which even heavy rains will not remove. The factories seem to vie with one another in the amount of smoke belched out of the stacks, although power-plants show better in this respect, while few factories seem to condense the exhaust from their engines. Fogs occur in Melbourne, and no doubt they are partly caused by dense smoke. I understand a movement is on foot to have all the factories shifted away from the city, although there would be huge compensations to pay, as the sugar refineries, superphosphate works, chemical works, tanneries, wool and hide warehouses are in large numbers. Taking a ride, one afternoon, in Sydney, I reached a suburb some miles out of town, and looking to the southwest, a whole line of factories could be seen pouring out smoke in quantity, so that there appeared to be a huge bank of it, like a cloud low down on the horizon. Sydney appears to have a dingy look about it, and this must be caused by rain and soot.

As Mr. Rickard remarked in his paper that the soot in London was due to incomplete combustion of coal used, so it is in the Australian cities. The waste, though not intentional, is quite serious, and reminds me of an article in *Power* some three months ago, written by a man who had visited certain factories indicating the engines, setting valves, etc., with much benefit to the owners. So it seems that a man might with profit to himself and others, give good advice on the proper combustion of coal in our cities. Power plants, as a rule, are worked with the greatest economy possible; and the engineers in charge of these works are known to be careful in this respect. A change in the method of firing, fireboxes, and perhaps the use of CO<sub>2</sub> recorders to check the work of firemen, might help matters somewhat.

M. W. VON BERNEWITZ.

Sydney, June 17.

### NEW YORK

LACK OF INTEREST IN MINING SHARES.—SITUATION IN METAL MARKETS.—REORGANIZATION OF MINING COMPANIES.

Both speculative and investment interest in mining concerns has been much restricted during the past week. In a general way there is little doing in the market, which is much in the doldrums. London cables tell of similar conditions prevailing in England, market review headlines reading 'Business in Mining Shares Declines Nearly to Vanishing Point.' In recent months Europe has been a heavy buyer of copper, but during the past fortnight has been almost entirely out of the market. Sellers who have not been sold well ahead have been getting under 17c., while some larger producers have been demanding 17¾c., though naturally making no sales at this figure. The copper situation is somewhat enlivened by the introduction of an element of uncertainty. The public is still trying to figure out the difference between mine production and refinery production, and the results differ widely in various calculations. The most striking feature in the copper situation has been the rooted unwillingness of the public to accept the improvement in the copper-metal market at its face value, and this has been emphasized by the vehemence with which the producers have declared themselves to have no knowledge of the sequestration of copper metal in any shape, form, or manner. Analysis of the refinery situation is pointed to as disclosing an inability to put out any increased amount of copper during the remainder of the current year. The Raritan plant of the International Smelting & Refining Co. is being enlarged, but during the process the output is somewhat curtailed. Much the same situation exists at Perth Amboy, and taking it all in all, copper producers are taking refuge behind the proposition that, regardless of the amount of blister copper that may be piled up in the stock-yards, it will be impossible for the refineries to turn out any greatly increased amount of copper in 1912. This may be somewhat comforting to the copper interest, but still leaves the public much in the dark as to the real situation of the metal. There has been a great deal of discussion concerning the recent drive made at the metal market. Whether or not the bears were acting in good faith is of minor importance. The fact is that the controlling interests in the present copper situation are the most important financial factors in the world, and are undoubtedly able to overcome the law of supply and demand if such a thing can ever be done. The silver market is becoming involved in conditions that somewhat resemble those governing the red metal. Some authorities are arguing that in the attempts of the speculators to accumulate stocks of silver in anticipation of demands to be made by both India and China, there has been created something akin to a silver surplus, and that unless speculators continue to protect their holdings by further purchases, the price of silver may be expected to remain stationary or decline. On the other hand, some of the best authorities estimate the world's consumption of new material at about 215,000,000 oz. annually, with an output of 225,000,000 oz., giving a margin of only 10,000,000 oz. for possible accumulations. From this it is contended that great importance must attach to requirements by the Oriental countries. The silver market in New York is at best only a secondary one, and while there has been some discussion from time to time regarding the possibility of speculation, there is as yet nothing that approaches an active market on this side of the water. The zinc market continues to break all previous records. This week saw a price of \$61 per ton for 60% ore, which is the highest level recorded.

The reorganization of Ohio Copper is proceeding along the lines mapped out by the reorganization committee. The latter has taken a rather shrewd turn in putting an upset

price of 25c. upon the outstanding stock. Undoubtedly this will induce a large percentage of the shareholders to stand the assessment of \$1 per share which is asked as an alternative. The thing most needed in Ohio Copper is a report by some engineer of unquestioned standing so that the shareholders may have some idea of what they own. The Heinze control has not been noticeably beneficial or particularly frank with the shareholders, and the result of the experiments by E. A. Wall have never been given out definitely. Between the two, Ohio stockholders have had to guess as to where they stood. Giroux remains a great deal of a mystery. The property is now shipping regularly to the Steptoe smelter, but the fact that it has reached the point of production is in no way reflected in the share market. It goes without saying that no one questions the strength of the Giroux, either as to finances or operating ability, but the stockholders would greatly appreciate a frank discussion of the reasons why Giroux has 'marked time' while other properties, such as Nevada Consolidated, in the same district, have made history. Granby Consolidated has 'come back' in a most encouraging manner. In June the company mined, in round numbers, 1,900,000 lb. of copper, and closed the first half of the current year with an output of 11,035,684 lb., the first full half-year's work the company has been enabled to do since the enforced shut-down. Granby's copper costs have been materially reduced, part of the time getting below 10c. per pound during the past six months. Aided by the improvement in the metal market, Granby is now piling up a treasury surplus against the requirements in behalf of the improvements to be made at the Hidden Creek ground, upon which some \$300,000 will be spent during the current year in work preliminary to the erection of a new smelter. The smelter will cost \$1,250,000, and this expenditure will be met by deferring dividends rather than going to the public for money. There is to be some reorganization of the Coppermines Co., which owns a large tract of mineral ground at Ely, Nevada, adjoining the Nevada Consolidated's Ruth mine. Mr. Armstrong has long been an associate of W. B. Thompson, and was an active member of the Thompson organization during the distribution of La Rose Consolidated. He has been engaged in many other Canadian enterprises, both in Cobalt and Porcupine. The Coppermines property, which includes the old Chainman and McKinley mines, were at one time held by the Gunn-Thompson group which operates the Mason Valley. H. F. J. Knobloch and E. N. Skinner, both associates of Mr. Thompson, are directors in the present Coppermines company. If, as may be surmised, Mr. Thompson is to make the Coppermines property a producer, it will give him a still more prominent place in copper circles. He is at present the controlling factor in the Mason Valley and the Inspiration Consolidated, and is evidently aiming to get together a string of copper mines to rival the Guggenheim list of porphyries. W. B. Thompson is given credit by Wall Street for a large share in the work done by J. D. Ryan and his associates in bringing about the present copper situation, and in that connection is now in touch with the greatest financial interests there are in this country. The reorganization of the Arizona Commercial can now be regarded as complete. Charles Sumner Smith, of Boston, the head of the new company and president of the Old Dominion Copper M. & S. Co., recently bought in the property at public vendue sale for the reorganization committee, and within a short time the shareholders will receive new stock for their old holdings. E. P. Earle, president of the Nipissing Mines Co., has recently been elected a director of the Tri-Bullion S. & D. Co., which owns and operates mines at Kelly, New Mexico. Tri-Bullion has long been traded in on the New York Curb, but has apparently never been taken very seriously. Mr. Earle's interests in the Southwest are increasing. As a copper-selling agent he handles the output of the South Utah Mines & Smelters, and as he is no longer connected with the La Rose in Cobalt, he is apparently transferring his field of activity from Canada to our own Southwest.

The engraved certificates of the Canadian Mining & Exploration Co. are now being issued. This is a concern recently organized, with capital of \$5,000,000, by some of the most prominent capitalists in the United States and Canada, as an exploitation company to take up new properties and examine and finance meritorious ones. The mining section of the open market in New York has been giving the larger portion of its attention recently to trading in the Tonopah issue. The recent discovery in the Tonopah Merger property is responsible for an advance in the issue to something better than \$1 per share. The Tonopah Merger Co. is headed by J. G. Butler, Jr., of Youngstown, Ohio, who was the controlling factor in the promotion of Ohio Tonopah, which latter company is now out of existence. Mr. Butler is a prominent steel-mill man in the Youngstown district. The controversy between the Clark interests and the Butte & Superior Mining Co. in Butte is to be adjusted by the simple method of exploring the orebodies that may possibly be involved, and, after investigation has determined the rights of the parties, settling on a compromise basis if necessary. This manner of treating mining disputes would not ordinarily appeal to the legal fraternity, but would certainly be of immense advantage to shareholders. The talk of litigation to be brought by Mr. Clark had a somewhat depressing effect on the Butte & Superior share market, the stock declining from about \$52 to something under \$40, at which level it found strong support.

### JOHANNESBURG, TRANSVAAL

DISAPPOINTING RESULTS OF NEW SHAFTS CUTTING THE MAIN REEF SERIES.—GOVERNMENT AREAS MORE PROMISING THAN RAND KLIPFONTEIN.

The most important recent mining event here has been the finding of the Main Reef at practically the same time by the Rand Klipfontein G. M. Co. and the North West-

ably lead to disturbances and disorderly scenes. However, the Brakpan Government Areas are considered the most valuable of these areas, but at the time they were offered, few tenders were put in, owing to the peculiar conditions and the large amount of working capital involved. For similar areas in the same neighborhood, no tenders were made when invited, as the ground was regarded as of more uncertain value than that now being developed by what are known as the State Mines. The ground occupied by the Government Areas near Brakpan was not drilled and proved by prospecting or pioneer bore-holes, as instead the reef had been proved practically on all the adjoining properties by either bore-holes or shafts. As this was the first time in the Transvaal that virgin ground had been opened without sinking preliminary bore-holes, the results were watched with all the more interest. On the Government Areas it was estimated that the Main Reef would be found somewhere between 2500 and 2600 ft. in depth, but as a matter of fact it was cut at a depth of 2395 ft., that is, a hundred feet shallower than expected, not a great difference when the surrounding circumstances are taken into consideration. The first intimation was that the reef was of good appearance and 27 in. wide. The situation of this particular shaft between Brakpan and the Modderfontein mines naturally led shareholders to expect that the reef would contain good ore, and some disappointment was felt when it was announced that the average assay worked out at 7.13 dwt. over 31 in. When everything, however, is taken into consideration, although the assay results failed to come up to popular expectations, there is not much reliance to place upon a single set of samples in such an extensive area, and after all it is equal in value to many other discoveries made in the same neighborhood. The real mining value of the reef will not be ascertained until some extensive driving has been done, and until the reef is opened any opinions formed as to its value will be necessarily premature. In such an extensive area there are bound to be considerable

variations in the value of the ore, as is the case in all the neighboring properties, but there is no reason to doubt that, taken over the whole area, the reef will be found, for the most part, to carry gold in payable quantities. Naturally, therefore, some importance will be attached to the results obtained in the other three shafts, one of which at least ought soon to reach the reef, so that while the first real disclosures of the Main Reef on the Government Areas may not be considered as equal to anticipation, it is better to suspend judgment as to the ultimate value of the property, not only until the

MAP OF THE EAST RAND.

ern shaft, one of the four shafts being sunk on what are known as the Government Areas lying between the Brakpan and Geduld mines on the Far Eastern Rand. This latter ground was leased in behalf of the Consolidated Investment Co. from the Transvaal Government under somewhat novel conditions. There are no promoters' or vendors' shares, all the capital subscribed being available for capital expenditure to be incurred in opening, developing, and equipping the property, the interest of the Government being met by a share of the profits governed by a sliding scale. These Government Areas take the place of public 'pegging' of claims on the Rand, owing, it is claimed, to the fact that these deep-level areas are unsuited to small mining concerns and public pegging would prob-

ably lead to disturbances and disorderly scenes. However, the Brakpan Government Areas are considered the most valuable of these areas, but at the time they were offered, few tenders were put in, owing to the peculiar conditions and the large amount of working capital involved. For similar areas in the same neighborhood, no tenders were made when invited, as the ground was regarded as of more uncertain value than that now being developed by what are known as the State Mines. The ground occupied by the Government Areas near Brakpan was not drilled and proved by prospecting or pioneer bore-holes, as instead the reef had been proved practically on all the adjoining properties by either bore-holes or shafts. As this was the first time in the Transvaal that virgin ground had been opened without sinking preliminary bore-holes, the results were watched with all the more interest. On the Government Areas it was estimated that the Main Reef would be found somewhere between 2500 and 2600 ft. in depth, but as a matter of fact it was cut at a depth of 2395 ft., that is, a hundred feet shallower than expected, not a great difference when the surrounding circumstances are taken into consideration. The first intimation was that the reef was of good appearance and 27 in. wide. The situation of this particular shaft between Brakpan and the Modderfontein mines naturally led shareholders to expect that the reef would contain good ore, and some disappointment was felt when it was announced that the average assay worked out at 7.13 dwt. over 31 in. When everything, however, is taken into consideration, although the assay results failed to come up to popular expectations, there is not much reliance to place upon a single set of samples in such an extensive area, and after all it is equal in value to many other discoveries made in the same neighborhood. The real mining value of the reef will not be ascertained until some extensive driving has been done, and until the reef is opened any opinions formed as to its value will be necessarily premature. In such an extensive area there are bound to be considerable

other shafts in course of sinking have reached the reef, but also until a fair amount of work has been done on the reef and its probable value thereby established. On the Rand Klipfontein property affairs are somewhat different, as this is situated some half dozen miles farther to the northeast and surrounded by properties carrying the Main Reef, but where the contents are uncertain. It is now about twenty years since the Main Reef Series was found on the farm Klipfontein at a time when comparatively little was known of the mining value of the Far Eastern Rand as Holfontein, Welgedacht, Geduld, Cloverfield, Grootvlei, Droogfontein, Daggafontein, Reitfontein, and even Brakpan were all unproved properties at that date. On Rand Klipfontein itself nearly twenty bore-holes have been put

down either to find the whereabouts of the reef or to ascertain the best portion of the property to select for mining operations, and these bore-holes have shown the reef to be of an erratic nature both as regards content and thickness. The selection of a mynpacht has therefore been attended with some difficulty, but, once selected, shaft-sinking operations were commenced. There has been some delay owing to the shaft encountering strong feeders of water, but at a depth of about 1800 ft. the Main Reef was unexpectedly cut, the width being announced at 54 in. The average assay result, however, over this width has been found to be only 2.18 dwt., although the nearest bore-hole No. 14, where the reef was found at 1886 ft. deep, showed the reef to assay 10 dwt. over 35 in., the reef just found in the shaft giving a result exactly the same as that of the thirteenth bore-hole. These results seem to confirm those generally observed along the fringe of the outcrop of the Main Reef Series in this part of the Far Eastern Rand, and on Holfontein, the adjoining farm, the highest assay obtained from the sample of the Main Reef Series was  $2\frac{3}{4}$  dwt., and that over a width of  $2\frac{1}{2}$  in. So far the outlook for the Rand Klipfontein is unsatisfactory, and even should better results be eventually obtained it is evident that only a small proportion of the ore can be expected to prove profitable.

### BLACK HILLS, SOUTH DAKOTA

BULLION OUTPUT OF DEADWOOD ASSAY OFFICE.—COMPANY MEETINGS.—LEASING ON THE PROPERTY OF THE GOLDEN REWARD.

The report of the United States assay office at Deadwood shows that the bullion purchased during the six months ended June 30 had a value of \$3,832,000. Adding to this the value of ore shipped to smelters outside of the Hills, and bullion marketed elsewhere, and the production of the district for the first half of 1912 will be very close to \$4,000,000, which establishes a record. On this basis the production for the year should exceed \$8,000,000, as the last six months of a year are usually better in the mining industry of this district than the first.

At the annual meeting of the Evans Consolidated company, held in Deadwood, July 17, the following directors were elected: D. Ellis Evans, Deadwood, president; H. Bischoff, Deadwood, vice-president and superintendent; J. L. Baker, Deadwood, secretary; Burt Rogers, Deadwood, treasurer; W. G. Giddings and J. F. Bickel, Racine, Wisconsin; A. D. Barnes, Waupaca, Wisconsin, and Neil McDonough, Deadwood. At the meeting 264,950 shares out of 350,250 shares outstanding, were represented in person and by proxy. The reports of officers showed the property to be in good shape, and practically ready for a mill. During the fiscal year of the company \$12,000 was spent in development, opening ore at a number of points. The old directors were re-elected at the annual meeting of the Wasp No. 2 Mining Co., and John Gray was re-appointed manager. The annual reports showed that the company had a prosperous year, the property operating steadily except for five weeks in January and February, when the severe cold weather interfered with work. The Victoria company announces that the development which has been in progress for the past year has proved the existence of sufficient ore to warrant starting the mill. One of the most important disclosures was the finding in the floor of the old workings a shoot of milling ore that has been traced for 400 ft. At other points in old workings, as well as in new work done, further orebodies have been developed. The ore occurs in the Carboniferous limestone and is an altered and silicified lime, easily treated by the cyanide process. The mill on the property is equipped for dry-crushing and leaching, having a capacity of approximately 200 tons per day. An aerial tram half a mile in length connects it with the mine, on the bluffs 600 ft. above. A spur of the C. B. & Q. railroad delivers coal to a bin above the boiler-room, and in other respects the property is well equipped for economical operation. O. N. Brown, of Deadwood, is superintendent.

Since adopting the leasing system on a portion of its territory, the Golden Reward company has had a large number of applications for the right to mine certain properties. The result has been that at present about half the ore-supply for the mill at Deadwood is coming from the lessees, the remainder being mined on company account. The mill is handling close to 300 tons per day. In each lease is a clause compelling the lessee to ship all of his milling-grade ore to the company's mill. Smelting grades are shipped out of the Hills. At present there are about nine or ten leases in operation (the number varies from month to month), and all of them are doing fairly well. Some of the best leases are held by Edward Manion, former superintendent of the Mogul property, who is extracting a good tonnage from the Alpha and Busco Bell mines. One property that has been reopened under the new system is the Wells Fargo, in Blacktail gulch. It is now a regular producer after having been idle for more than twelve years. The North Homestake company is developing on the 620-ft. level, cross-cutting both east and west. Up to date a total of 450 ft. of work has been done on this level, with encouraging results. When the shaft was started from the 220-ft. level it was given out that the work was planned to exploit orebodies that had been discarded in diamond-drilling. D. D. Findley is cleaning up the old Golden Reward smelter, at Deadwood, and has shipped several cars of material, which have yielded good returns. Mr. Findley has also secured the privilege of cleaning up several other plants in the Hills, and expects to remain several months. R. L. Daugherty, State Mine Inspector, has started the work of compiling data for his annual report, and has been engaged for the past few weeks in an examination of the Homestake mine at Lead. He expects to be busy until late in the fall in order to cover his territory and secure all of the information which his detailed report calls for.

### LONDON

REPORT OF THE ST. JOHN DEL REY.—CHANGE FROM STEAM TO ELECTRIC POWER.—IMPROVED METHOD OF VENTILATION.

The reports issued by the company owning the St. John del Rey gold mine in Brazil are always of interest, for this is the oldest and deepest gold mine in the world. The production of gold for the year ended February 29 last was the largest obtained in any year since the company began operations in 1834. During the year, 169,310 tons of ore was raised, and after the rejection of 2% waste, 196,600 tons was sent to the 130 stamps. The total yield was £442,142, or 45s. 10d. per ton, of which 29s. 9d. was recovered by amalgamation and 16s. 1d. by cyanidation. The working cost, including development, London expenses, and taxes in Brazil, was £301,753, or 31s. 3d. per ton. In addition, £24,794 has been transferred to capital expenditure account, £2891 paid as directors' percentage, £7615 as English income tax, £36,275 in redemption of mortgage debentures, and £4504 as interest on debentures. The preference shareholders receive the usual 10%, absorbing £10,000, and the ordinary shareholders £54,626, being at the rate of 10%. The adit, 1100 ft. long, on horizon No. 16, connecting the bottom of 'F' shaft to the top of the proposed 'G' shaft, has been completed, and the hoisting engines will be installed when the foundation is ready. The sinking of 'G' shaft will then be begun, and it should be down 600 ft. to horizon No. 18 early next year. It is intended to sink it eventually another 600 ft. to horizon No. 20, 5800 ft. below adit, or 6100 ft. below surface, provided the lode continues profitable. The present horizon No. 17 is the deepest working. The ore reserve on February 29 was estimated at over 1,000,000 tons, sufficient to keep the mill employed for five years. The change from steam to electric power is being gradually effected, and a second unit of electrical plant for the Peixe river hydro-electric station has been shipped. With the workings extending to so great a depth, the question of temperature is of urgent importance.

George Chalmers has published additional information of importance in his yearly report. During the past year, particular attention has been paid to ventilation, with results that are encouraging, and during the current year further reductions may be confidently predicted. The old Capell fan, that did duty for many years, has been replaced by new Sirocco fans, each of which is driven by a 150-hp. electric motor. One of these was started on February 20, and the air in the lower workings was immediately rendered less hot and stuffy. Mr. Chalmers' chart showing the mean temperatures during the four hot months, December to March, of 1910-11 and 1911-12, proves that the rock and air temperatures have been appreciably reduced, and next year, when the whole of the ventilation will be done by the new fans, there should be a further substantial reduction. In the chart, a line drawn through points representing the

continued prosperity of this mine must be grateful to Mr. Chalmers, who has been manager for so many years. About twenty-five years ago the conditions of the workings became very bad and additional capital had to be raised and a new system of mining introduced.

### JOPLIN, MISSOURI

ZINC PRICES CONTINUE TO RISE, AND NEW RECORDS ARE ESTABLISHED.—AMERICAN ZINC, LEAD & SMELTING CO. EXTENDS ITS HOLDINGS.—IMPORTANCE OF KEEPING RECORDS OF DRILLING AND DRIVING.—ZINC AND LEAD NOTES.

The highest prices for zinc ore in the history of the district prevailed the latter part of July, when 60% grades

MORRO VELHO MINE OF THE ST. JOHN DEL REY M. CO., LTD.

rock temperatures at horizons No. 14 and 17 when first opened, reaches horizon No. 22, 6500 ft. from surface at 117°F. On the other hand, a line through the points recording the temperatures after the introduction of ventilation in the upper levels, may be taken to represent the ultimate air temperature of the workings obtainable by the use of suitable ventilating apparatus. At 6500 ft. the temperature would be 95°F. The rock temperatures are taken at the bottom of 10-ft. holes, and those of the air in the downcast. A further improvement is being made by Mr. Chalmers for the purpose of avoiding the chilling of the workmen as they leave the mine. At present the incoming air is drawn through the adit, and when the men, leaving after the night shift, walk along the adit they face the full current of incoming air at a temperature of perhaps 50°F. lower than that of their working place. In future the air is to be drawn into the mine from the surface through shaft 'D' instead of through the adit. The

commanded as high as \$60.50 per ton, meaning a settlement of from \$3 to \$4 more than this figure for choice lots carrying high percentages of metallic zinc. Spelter, East St. Louis quotations, likewise reached its highest record, \$7.20 being paid. As a result of the high prices, coupled with the fact that metal bookings have been made up to next October at unusually high figures, great activity is noticeable in every part of the district. The highest price of previous years was \$57, basis, in 1905. This year the market began strengthening early in March, and in June the then high record of \$58.50, basis, was attained. During the latter part of July almost every smelting concern buying ore in the Joplin district paid as high as \$58, while the majority paid \$60 and \$60.50.

A 40-acre lease of the J. W. Boyd land at Sarcoux, Missouri, on which the Cameron 400-ton mill is situated, has been taken under option by the American Zinc, Lead & Smelting Co., the largest mining and smelting company

in the district. Options on 200 acres adjoining likewise have been taken by the company, and mill and ground tests are now being made. The American company, which at first confined its mining operations in this district to the thin sheet-ground zone at Prosperity, has extended its field of operations to many camps and now owns in fee or controls leases at the following places: Prosperity, Webb City, Duenweg, Joplin, Central City, Wentworth, and Sarcoux. This company alone produces about one-tenth of the total tonnage of blende concentrate from the entire district. Extensive drilling operations in this district have virtually gone to waste because, with few exceptions, no drill records have been kept. The same applies to shaft-sinking and to driving. The need of keeping development records applies to any other mining district as well as Joplin, but it would be difficult to find a place where the keeping of records has been considered of so little importance as in Joplin and adjacent territory. High prices for ore have stimulated prospecting, and numerous leases that have been drilled and re-drilled are being prospected again. All the records of these new holes should be kept. Had the prospectors the records of previous drillers, they would be aided materially in determining the nature of their ground. Operators are just awakening to the importance of a study of geological formations in connection with their development. Knowledge of rock formations has proved of untold value in finding paying mines. As all the drilling in the district, with the exception of one company's operations, is done with churn-drills, it is rather difficult to keep complete records of actual clippings, but even if these cannot be preserved, logs could be retained, and these would prove valuable. It occurs frequently that operators go into abandoned ground, defray heavy pumping expenses, and waste much valuable time in trying to get ore from old drifts in which no ore ever existed. Mineral-laden dump-piles are misleading and often cause useless work in old workings that have remained idle for years and about which little can be learned because of the absence of any kind of records.

A rich body of zincblende in soft ground has been found by the Betsy Jane Mining Co., sinking a shaft on the Spencer land. Ore was found at 147 ft. and extended to 162 ft., at which level a drift is being started. The company has only meagre hoisting equipment at present. The quality of the ore is really phenomenally high, tubs of almost pure zincblende being hoisted out. The quality of the blende will run better than 63% metallic zinc. The company intends to determine first whether the orebody is as extensive as indicated by several drill-holes put down. By this time the crush pile should be big enough to warrant the construction of a mill, if the ore continues rich.

### BUTTE, MONTANA

NEW OWNERS FOR THE LA FRANCE COPPER CO.—RUMORS AFFECT BUTTE & SUPERIOR STOCK.—NEW OREBODY IN THE NORTH BUTTE.

The property of the La France Copper Co. has passed into the hands of the Lincoln Trust Co. of New York, and this would seem to indicate that the reorganization plans will go into effect in a very short time. The La France Copper Co. was organized by F. Augustus Heinze, and in time Heinze and his associates negotiated a loan with the Lincoln Trust Co. for \$2,000,000 on the property. The copper company having defaulted in the interest, and having made no provision for the principal, the trust company foreclosed, and a few days ago the La France company filed an answer to the suit acknowledging all the allegations contained therein and consented to an entry of judgment in favor of the trust company. A report on the Lexington mine, which is one of the properties included in the mortgage, is understood to have been favorable, and a movement was at once started to secure possession and reorganize the company and to eliminate F. A. Heinze. The property included in the mortgage consisted of the

following lode claims: Lexington, Louise, Angela, Wild Pat, Atlantic, Wapalle, and Allie Brown, with millsite and buildings, improvements, and machinery. At one time all the property belonging to the La France company was said to have a value of about \$10,000,000. Like other properties in this district showing high-grade zinc ore, the Lexington is a valuable property, but the question which the new company will have to face is the securing of a process that will remove the iron from the ore. The Basin Reduction Works is also the property of the La France company, but before it can be utilized for the treatment of ore, machinery will have to be purchased, as all that was of any great value was removed a considerable time ago by Mr. Heinze to the Ohio plant, while the machinery used by the Butte & Superior company when that organization had a lease on the place, was owned by it and removed to this city and placed in that company's new concentrator.

The decline in Butte & Superior stock at times during the past two weeks has put in circulation rumors which have had an influence on the market. There has been the statement, denied by Butte & Superior people, and then repeated by persons who think they have some inside information, to the effect that litigation was possible between the company and W. A. Clark, the owner of the Elm Orlu mine, which adjoins the Butte & Superior property. Then came a report to the effect that the new concentrator was not recovering anything like the amount sent out in despatches to Eastern financial papers, and another story was to the effect that Hayden, Stone & Co., who floated the bonds of the company, were selling the stock. A. B. Wolvin, president of the Butte & Superior company, who has been in the city for several weeks, when asked concerning the various rumors, denied them all. He said that the mine was in first-class condition and that the new concentrator was giving satisfaction. During the time the mill had been operated, there had been a saving of 90% of the mineral content of the ore. For the past few weeks it has been impossible to operate the concentrator to its 500-ton capacity, owing to a lack of water. At first it was thought the water from the Black Rock mine would be sufficient to supply the concentrator, but this has been found insufficient, and the deficiency has to be made up from the Butte city water system. Some changes have been in progress and at times during the day the city water-supply had to be cut off, thus necessitating a decrease in the capacity of the mill. Mr. Wolvin claims that at the rate the concentrator has been operated it has been clearly demonstrated that it will be fully up to the requirements. The new hoist is expected in a few days, and during the time it is being placed the mill will be kept in operation from ore already brought to the surface. Development on the 2400-ft. level of the Snowball vein of the North Butte company now leaves no doubt as to the richness of the orebody recently opened. The cross-cut is about 7 ft. wide and will average 8% copper with 10 oz. in silver per ton. Cross-cutting on the 2800-ft. level is still proceeding and, according to estimates, the Jessie vein ought to be intersected in about one week. The North Butte property makes an improved showing on the strength of this discovery. The mill of the Bald Butte Mining & Milling Co. has resumed operation after being closed down for nearly four years. There was some difficulty among the stockholders, and a receiver was appointed, which resulted in the sale of the property, a year ago, to Boston and New York capitalists. The mine was worked and some good ore uncovered a short time ago in new ground, the assays proving satisfactory. Sufficient ore has now been blocked out to ensure the operation of 20 stamps of the mill for some time, and the indications are that in a short time more stamps will be required. W. E. Stone, of Boston; John Rapelje, of Hopewell Junction, New York; W. M. Beleher, C. M. Newell, G. R. Chandler, and E. W. Orswell, all of Boston, are the directors of the company. W. E. Stone is president of the company, John Rapelje vice-president, and W. M. Beleher secretary and treasurer.

## General Mining News

### ALASKA

#### COPPER RIVER

The Bonanza Gold Mining Co. is planning the purchase of a 5-stamp mill for the treatment of a recently discovered orebody. A shipment of 32 sacks of ore from one of the veins cut by the adit was made to the Tacoma smelter, and returns from a mill test were \$202 per ton in gold and silver. The adit has been driven 306 ft. without cutting the main vein which outcrops 187 ft. above the mouth of the adit. The management intends also to build a tramway to convey the ore a distance of 1275 ft. down to the mill-site. The new mill will be operated by water-power in the summer and by steam in the winter.

### ARIZONA

#### COCHISE COUNTY

The Montana-Tonopah Mines Co. has announced its intention of building a mill at Pearce for the treatment of ore from the Commonwealth mine. Work on the foundations will be commenced in August, and specifications for the mill are now being drawn. The plant will consist of 30 stamps, two tube-mills, and a cyanide mill. The estimated capacity is 300 tons per day, and the cost is estimated at \$200,000.

#### GILA COUNTY

(Special Correspondence.)—The production of the Miami Copper Co. for June was 2,683,310 lb. During the month 4964 ft. of development was done. The development of the Captain orebody, which is a tongue of ore extending out from the main orebody, is about to begin. Equipment will be erected at the now dismantled Captain shaft, which will be connected with the main shaft by a drift from the main orebody on the 420-ft. level. Waste rock from development will be hoisted through the Captain shaft and ore will be trammed on the 420-ft. level to the main shaft. It is estimated that the Captain orebody contains about 3,000,000 tons of ore. A second churn-drill will soon be put to work on the northeastern part of the property, where another large body of ore, assaying from 1 to 1 3/4% copper, has already been proved. Exploration of the ground below the 570-ft. level is being continued by diamond-drilling. Churn-drill hole No. 2 of the South Like Oak Development Co. is over 400 ft. deep in granite. Superior & Boston has begun to ship ore from the Limestone vein and shipments from the Great Eastern vein continue. Working time of churn-drillers and their helpers at the mines of the Miami district has been reduced from 12 to 8 hours per day. Drillers will receive \$5 and helpers \$4 per day. The new scale went into effect July 15. It is reported that the drift on the California vein at the Copper Reef mine, near San Carlos, has passed through the fault recently encountered and entered vein-matter carrying copper, gold, and silver. Samples from the vein are being assayed.

Globe, July 20.

The output of copper by the Old Dominion mine in June was 2,130,000 lb., making a total of 12,973,000 lb. for the half year, as compared with 13,841,800 lb. in the first six months of 1911, 13,430,000 lb. in 1910, and 18,790,000 lb. in 1909. It is expected that three furnaces will be kept in operation from now on, as the amount of custom ore received is gradually increasing under the stimulus of the present high copper prices, and the mine production will probably be slightly increased. The new dust chamber for the converter plant is finished.

#### GRAHAM COUNTY

The Shannon Copper Co. reports for June a production of 1,270,000 lb. of copper, as compared with 1,464,000 lb. in May. For the half-year the output was 8,516,000 lb., against 7,314,000 lb. last year. The mine earnings for the quarter ended May 31 were \$222,194, and for the railroad \$8851, making a total of \$231,046. The new management

has reduced the operating costs; has improved the smelting plant and railroad, and has retired the bonds of the company.

#### MARICOPA COUNTY

At the Vulture mine, development has rediscovered the orebody which was cut off by a vertical fault, nearly parallel with the strike of the vein. A winze from the 750-ft. level has cut the vein and proved the displacement to be 300 ft. The first stope which was opened for the full width of the vein was 29 ft. wide. The 100-ton mill has been operating steadily since February, and the average value of the ore treated from development has increased. During June the ore treated at the mill assayed \$25.85 per ton.

### CALIFORNIA

#### AMADOR COUNTY

A head-frame has been erected on the Memphis mine in the Plymouth district, and it is intended to sink to 300 ft. It is proposed to increase the capital of the company, and thoroughly develop the property.

#### CALAVERAS COUNTY

Regular shipments of ore are being sent by the Calaveras Copper Co. to the Campo Seco plant of the Penn Mining Co. Another stope has been opened in rich ore. A preliminary survey is to be started for the construction of a 12-mile narrow-gauge railroad to connect this mine with the Sierra line, at Chinese Camp. This road could be built in a few months and would help to reduce costs. The smelter of the Calaveras company is well on toward completion, and one furnace may be blown in next month. One of the features of the new plant is the heating of the blast by the waste heat of the furnace, from which great economy is expected.

#### INYO COUNTY

The Loretta mine, on the west side of Eureka valley, is to be developed into a producing property under the direction of John G. Kirchen, of Tonopah, who is acting for Charles M. Schwab and associates. This property was originally discovered by William Eva in December 1879, and was then located as the Neptune. The Loretta company was organized in 1896, and since then development has been carried on intermittently. The outcrop of the orebody extends across the face of the hill. The shaft was started 150 ft. lower and is now 865 ft. deep, about 1000 ft. under the apex. The width of the vein varies between 30 and 80 ft., and two narrow parallel stringers dip toward the main vein at distances of 40 and 60 ft. The shaft at its present depth has just cut through the foot-wall of the vein, and development has opened large orebodies at the 400, 550-ft., and bottom levels. In the earlier work two adits were driven in the upper part of the vein, disclosing ore about 70 ft. in width. The average value of the ore so far discovered is placed at 4 to 5% copper and about \$3 in gold per ton. At intervals of 5 to 20 ft. rich streaks are found, up to 3 ft. wide, with ore as high as 50% copper. The ore is silicious, but carries some specular iron. No stoping has been done, as all work has been concentrated on the development, and blocking the ore. About 20 men have been employed at the mine. A contract recently negotiated with the Nevada-California Power Co. provides for a line from the Goldfield wires at Gilbert hill, a distance of 15 miles, to be completed in 90 days. A 100-hp. electric hoist will replace the 25-hp. distillate engine and hoist, and will provide power for further sinking. The management has the promise of \$2,000,000 for development from Mr. Schwab. Several working plans have been considered. One is a railroad from Coaldale, 60 miles distant. Another calls for a method of transportation to the Southern Pacific railway in Owens valley, joining that road between Laws and Alford, and shipping ore to a smelter elsewhere. A third plan is the erection of a smelter at Oasis. The building of a smelter near the mine has not been considered, on account of the damage to vegetation from the fume. The

company at present owns claims covering an area 3000 ft. wide and over two miles long, and has planned the working of the orebodies on a large scale.

#### MODOC COUNTY

The first shipment from the High Grade district from the Sunshine mine yielded an average of \$286 per ton at the Selby smelter.

#### SHASTA COUNTY

A fire at the Little Nellie mine, between Keswick and Iron Mountain, on July 21, destroyed the compressor house, blacksmith-shop, and stable. The loss amounted to about \$3000 and the mine will be closed until the compressor plant can be replaced. Twenty men will be thrown out of employment by the fire, the cause of which is unknown.

The last of the coke and silicious ore from the yards and bunkers of the Balaklala Con. Copper Co. at Coram has been shipped to the Mammoth smelter at Kennett, and the small force of men who have been employed in loading the ore has been discharged. The masonry about the smelter is gradually crumbling, and extensive repairs would be necessary before operation could be resumed. A part of the bell of the chimney has fallen, and the whole structure is cracked from top to bottom. Several hundred feet of the new flue built in connection with the Cottrell process has fallen, and the entire wall on the west side is in ruins. The condition of the underground workings of the mine is also considered serious, and it is believed that many caves have taken place since the suspension of operations.

#### SISKIYOU COUNTY

(Special Correspondence.)—Arrangements have been completed for the reopening of the Black Bear quartz mine, Salmon River district. A small force is at work and a new shaft will be sunk. The property recently passed under the control of Eastern capitalists, represented by Benjamin F. Daggett. The property has been idle several years. It is claimed to have produced nearly \$4,000,000. It is reported that work is to be resumed shortly at the King Solomon, of which Wayland H. Young is manager. Important developments are reported at the Foster mine, Trail Creek district. The vein ranges from 3 to 5 ft. wide, with assay returns from the ore averaging around \$20 per ton. Two Huntington mills are in use, handling about 15 tons per day. Hannon & Fippon have arranged to build a pipe-line and giant on their Slide creek placers. Two ore-shoots have been opened, and will also be worked. Two giants are in commission at the Smith Parker hydraulic claim, on the South Fork of Salmon. Water facilities have been excellent this year, and a profitable and expected season is expected. A. Maltman, James Finnerty, Hugh Lambert, and A. E. Pomery report the development of a promising discovery near Gazelle. The vein has been intersected by six cross-cuts, and varies from 15 to 22 ft. in width. Assays of the ore average \$6 to \$8 per ton. Robert Parker announces the discovery of the old gravel channel on Kangaroo creek, after a two years' search. A giant will be placed at the beginning of the rainy season. It is estimated that the Shumway hydraulic mine, on the Forks of Salmon, yielded about \$50,000 during the past year. It is one of the largest active hydraulic properties in the county. French and San Francisco capital is interested. Placer mining is active throughout the Salmon River district, while quartz deposits are claiming considerable attention. It is rumored Eastern people are negotiating for the valuable Beaudry placers, but official confirmation is still awaited.

Etna, July 19.

The Southern Oregon and Northern California Mining Congress, held at Yreka, brought its fourth semi-annual meeting to a close on July 20. A good session was held, and resolutions adopted recommending a simplified procedure governing the procuring of patents to mineral lands; commending the work of the American Mining Congress in the legislative creation of the Bureau of Mines, and the assistance of the latter to mining; also commending the United States Geological Survey, and the Mining Bureaus

of California and Oregon; reduced rates on railroads for minerals and investigation by the Interstate Commerce Commission of existing freight rates in the district; and a more liberal interpretation of mineral land laws relative to the use of timber and water. The Congress pledged itself to fight wild-cat mining schemes. Several good exhibits were shown at the Congress from various mines, and products from the Heroult electric furnace attracted general attention. The next meeting will be at Redding, in May.

### COLORADO

#### LAKE COUNTY

At the Mount Champion mine the main adit is in some 500 ft., and No. 1 about 200 ft., both being connected by a raise of 160 ft., which is in 400 ft. from the entrance to No. 4. About 50 men are employed. Work at the mill and aerial tramway is being pushed. At present all supplies are hauled to the mine by teams. The main adit of the Miller company is in 450 ft., while a second one has been driven 300 ft. The two are connected. There are said to be ten veins in the property from 5 to 10 ft. wide, and the ore milled and smelted assays high in gold and silver. Thirty-five men are employed and 1200 tons per month is mined. There is a good surface plant and aerial tramway.

#### SAN JUAN COUNTY

(Special Correspondence.)—Reports from Rico, in the San Juan district, are favorable. The Rico Argentine and the Rico-Wellington group of claims, the latter owned by the Jesse Knight interests, are doing development, and are shipping ore to Salt Lake smelters. A great deal of zinky ore is being found, and it seems probable that some system of concentration will be used in order to make the handling of the low-grade ores profitable. A fire occurred on June 30 at the Silver Lake mine, near Silverton, owned by the American S. & R. Co. Practically all the mine buildings were destroyed, except the boarding house, which was saved by dynamiting smaller buildings between it and the blacksmith shop, where the fire started. The upper terminal of the tramway was destroyed, necessitating the closing of the mill. Until repairs have been made no ore can be shipped to the Durango smelter. The loss is reported at \$30,000. The Eagle M. & M. Co. is developing a zinc mine near Red Cliff. The old Iron Mask mine, which was famous for its lead carbonate and silver ores during the early days of Leadville, had been found to contain an irregular body of zinc sulphide in the form of a replacement in limestone. This ore is being concentrated and shipped to Bartlesville, Oklahoma, for reduction. The company is also operating the Rocky Point mine, which is producing silicious gold ore. In the same district, the Bleak House mine is being worked for the same classes of ore found in the Iron Mask and Rocky Point. Here the zinc ore is found as a regular bed in the limestone strata, and the silver ore in vertical fissures in the quartzite formation below limestone.

Denver, July 20.

#### TELLER COUNTY

It is intended by the El Oro company to erect a mill in Eclipse gulch. The Rex mill, known as the Homestake, may be purchased and removed. Whatever mill is built will be modeled on the lines of the Gaylord and Wild Horse plants in the district, although finer grinding may be used. The No. 2 shaft of the Portland mine is down 1588 ft. Water is expected to be encountered within a few days. From the 1600-ft. level it is intended to develop the ore now being extracted at the 1500-ft. level. The shaft will be sunk until the water is reached, and at that point, whether 1610 or 1650, laterals will be run. The present output to the Portland mill at Colorado Springs is between six and seven cars per day.

The twentieth annual convention of the Western Federation of Miners was held at Cripple Creek, beginning July 16. Charles H. Moyer, president of the union, presided, and was supported by a large majority of the delegates against an attack made by a part of the Butte delegation.

A resolution calling for a proposed minimum wage scale of \$4 was voted down.

## MONTANA

### MADISON COUNTY

The Butte-Virginia company is to start milling the ore from the Bell group of claims, near Virginia City. Ore is being hauled to the Grant mill, one mile distant from the mine, at the rate of 40 tons per day. The mill consists of a crusher, 15 stamps, vanners, and cyanide plant, driven by a motor. About 30 men will be employed at the mine and mill. F. H. Edwards is in charge of the latter.

## NEVADA

### ESMERALDA COUNTY

Sinking has been resumed in the winze of the Goldfield-Belmont, which has yielded a considerable quantity of ore. It will be sunk to 450 ft. to enable prospecting the lode exposed in the upper levels. The pump installed, easily deals with the water in the winze. Little water was found down to 400 ft., but on extending the drift on the 350-ft. level, the dike that apparently cuts off the water in that part of the mine was penetrated.

### HUMBOLDT COUNTY

Through a cloudburst last week, 20 people were killed at Mazuma, and about \$40,000 damage was done to the Seven Troughs Coalition Mines' property. It is stated that a wall of water 15 ft. high flowed down the canyon, and it was impossible to inform the residents of the former place. A concrete wall, 14 by 18 ft., around the mine tailing dump, was washed away; while part of the cyanide plant and a strong room containing over \$10,000 in gold were also lost. The damage can be repaired in about 30 days. The mine was not damaged in any way.

### LYON COUNTY

(Special Correspondence.)—The McConnell mine, south-east of the Mason Valley, is shipping copper ore at the rate of 75 tons per day to the smelter at Thompson. The mine is owned and operated by Elbert & Sonne. At the smelter the esocnd blast-furnace, which has not yet been blown in, is being extended to 30 ft. by the addition of another section of jacket, in order to take care of the increased tonnage of ore which is coming to the plant. When this furnace is blown in the No. 1 furnace will be blown out and extended to 35 ft. in length. The plant is now smelting 750 to 800 tons per day, chiefly from the Nevada-Douglas, Mason Valley, and McConnell mines, though smaller shipments are being received from the Malachite, the Northern Light, and the Empire of Nevada. The Yerington Copper Co., which has been making shipments to the Thompson smelter, has arranged to ship its high-grade copper ore to the smelter at Garfield. The properties around Luning are also shipping to the Thompson smelter and the Luning Gold Mines Co. has sent out seven earloads recently, yielding about \$25 per ton. It is reported that higher grade ore is now being taken out. R. B. Todd is in charge. The reasonable treatment rates of the Mason Valley smelter are proving a great stimulus to prospecting in adjacent districts.

Mason, July 22.

### MINERAL COUNTY

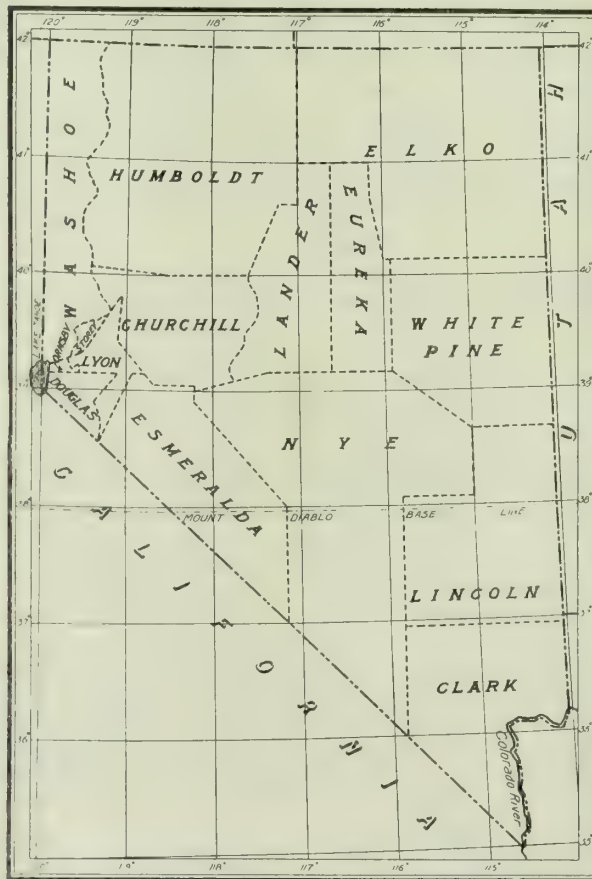

Twelve claims are being developed in the Luning district, and parcels sent to the smelter at Thompson have yielded about 8% copper. Transportation of ore is hindered by lack of teams. Activity is general throughout the district.

### NYE COUNTY

The report for June of the Tonopah-Belmont Development Co. gives the ore milled as 7370 tons, from which 2568 oz. of gold bullion and 258,301 oz. of silver bullion were produced. The net value of the ore was \$204,602, and the net profits for the month, \$125,525. No ore was shipped to smelters, and the tonnage treated was less by 586 tons than in the preceding month. The company has decided to sink the main shaft to the 14th level. On the 13th level stopes are being cut out in the east drift on the Belmont vein, and the west drift on the Belmont vein

is in good ore. Ore for the mill at Millers is hoisted through the Desert Queen shaft from all levels, from the 900 to the 1166-ft., inclusive, while ore for the new mill is hoisted from the 12th and 13th levels. This ore is crushed and then stored in the mill-bins, which are now nearly filled and ready for the starting of the stamps. The June report of the Tonopah Mining Co. shows that 14,551 tons was milled, with an average value of \$18.95 per ton. The total output of gold and silver bullion was 259,180 oz., with a value of \$210,500. In addition, 91 tons of concentrate, valued at \$36,900, was shipped. The net profit for June was \$151,389. Prospecting is being continued by the company, and some improvement in the value of the ore is noted, although no new orebodies have been found.

The Montana-Tonopah company has ordered another Trent agitator, which will be placed in the mill as soon

MAP OF NEVADA.

as possible. With this increased capacity of the cyanide plant, it is hoped that the efficiency of the mill will be raised and a better recovery made from the high-grade ore which is treated in the mill. The Railroad Valley company, organized in Tonopah about a year ago as the successor to the Railroad Valley Saline Co., announces that the main purpose of the company is to conduct a comprehensive search for potash-salt deposits that may exist in the buried saline residues of former lakes of the desert basin; also to acquire such deposits and establish experimentally their commercial value. If any workable deposits are acquired, they are to be sold or leased to an operating company under control of an American fertilizer concern. Tentative negotiations have already been initiated with the fertilizer companies and are subject to ratification at the proper time by the stockholders of the Railroad Valley company. Incidentally, this company proposes to develop and realize upon any agricultural or other valuable asset that may be created by its drilling operations. The directors of the company are Clyde A. Heller, president of the Tonopah-Belmont company; Max J. Brandenstein and James T. Donahue of San Francisco, and Eugene Howell, W. W. Charles, and Hugh H. Brown of Tonopah. In their an-

nouncement the directors frankly state that they regard the exploitation for potash as an attractive gamble. If successful, the company hopes to make immense and long-continued profits by transferring commercially workable properties to fertilizer interests powerful enough to establish an American industry against German competition. If the potash exploration proves a complete failure, it is believed that the value of the agricultural land, controlled by the company through the artesian water-supply proved by a 900-ft. drill-hole, will be great enough to return full value to the shareholders. The company has engaged the future services of Edward E. Free, at present special agent of the U. S. Bureau of Soils, to take charge of the exploration work. The drill-hole which at its present depth has developed several flows of artesian fresh water is expected to develop artesian salt water at a depth of 1200 to 1500 ft., and it is believed that a large tonnage of potash will be found in solution under conditions which will deliver to the surface, without any mining expense, a brine containing a commercial percentage of potassium chloride.

During a thunderstorm at Tonopah on July 20, lightning struck and damaged the MacNamara mill, causing a shut-down for a few days. A carpenter was electrocuted at the Umatilla mine.

#### STOREY COUNTY

(Special Correspondence.)—The Ophir has begun to level off the site for the cyanide plant to treat its tailing. From the milling of the Ophir ore in the Kinkhead mill a large tonnage of tailing assaying \$5 to \$6 per ton has been impounded. The cyanide plant which, it is reported, will have a capacity of 100 tons per day and will comprise tube-mills, Trent agitators, and Butters filters, will be used to treat this tailing. The Mexican mill is now cyaniding 85 tons per day of ore assaying \$20 to \$40 per ton, at a cost of less than \$2.75 per ton. The Oliver filter, which at first gave trouble from the high content of the tailing, has been modified by the addition of more sprays of wash water and is giving excellent satisfaction. The Pumping Association is installing three new 1500-gal. electric turbines at the bottom of the C. & C. shaft to replace the hydraulic elevators now in use. On the 2000-ft. level of the Julia Whitman Symmes, the superintendent, has a diamond-drill at work searching for the dacite dike which accompanies the orebody. The Nevada Deep Mines Co. has constructed a cyanide plant on the Carson river a short distance east of Dayton. The plant is connected with the mine by a wire-rope tramway.

Virginia City, July 20.

At the Comstock mines, the Ophir company is out 430 ft. in the southwest drift of the 2500-ft. level. Nineteen cars of ore, assaying \$14.42 per ton, were taken from the stopes of the 2100-ft. level. The Consolidated Virginia has its south drift started 100 ft. from the mouth of the west cross-cut, out 166 ft. in porphyry and quartz of low assay. On the 2500-ft. level of the Union Consolidated, the northeast drift is out 130 ft., and shows 15 in. of quartz, besides 30 in. of broken ground. Assays gave from \$1.30 to \$7.70 per ton.

At the Yellow Jacket the west cross-cut from 1100 ft. was out 142 ft. The water in the C. & C. shaft was down 293 ft. below the 2200 station; and in the Ward shaft, owing to an increase in the water in the south drift in Bullion ground, large pumps and discharge pipes have been installed. In the pump compartment of the shaft an 8-in. pump column and connections have been put in for pumping below 2100 feet.

Two new transformers have been installed in the sub-station of the Truckee River Electric Co. at Virginia City. They are necessary to supply the increase of 1200 hp. used on the new pumps at the C. & C. shaft. It is said that a new line is to connect the sub-station with the 60,000-volt line which is to supply the Thompson smelter and mines. Four different lines would be then available for Virginia City. Practically all new equipment on the mines will be electrically driven.

Last Friday the ground around the old glory hole of the Chollar mine settled and left cracks several inches wide. The ground seems to be settling toward the hole, which is some 30 or 40 ft. deep, and about 100 ft. diam. at the top. The movement is 150 ft. from the present nearest workings of the mine, and is probably due to an old stope caving in. There have been cracks on the mountain side for some years, but they have not opened much.

#### WHITE PINE COUNTY

The report of the Nevada Consolidated Copper Co. for the first quarter of 1912 shows that 821,421 tons of ore was treated, producing 17,578,000 lb. of copper. The gross value of the output was \$2,838,918.50. The cost of mining was \$0.682 per ton, of transportation \$0.264, and of reduction \$1.623. The net yield for the three months was \$729,087.81. During the second quarter the production was 18,092,000 lb. of copper. The Jack shaft of the Nevada Consolidated is now down 690 ft., 66 ft. having been sunk during the last 30 days, and this rate of sinking should be maintained until the 800-ft. level is reached. A little low-grade copper ore was found in sinking. From this shaft the ore found in the 500 and 800-ft. levels of the mine can be developed easily. About 100 gal. of water per minute is being pumped from the shaft.

#### NEW MEXICO

##### SOCORRO COUNTY

(Special Correspondence.)—A fire at the Deadwood Mines on July 5 destroyed the shaft-house and head-frame, and damaged the machinery. Work on a new structure was started at once and underground work will be resumed this week. The mill has operated largely on custom ore since the fire. A 50-hp. gasoline engine is being added to the mill power-plant. At the Socorro Mines special ore-bins have been erected for the accommodation of custom ore that will be delivered from adjacent claims. The mill is operating regularly on about 175 tons daily capacity.

Mogollon, July 19.

#### OREGON

##### BAKER COUNTY

(Special Correspondence.)—The Virtue Mines Development Co. has completed the first half of its cyanide plant, and is now working on mill tailing, handling 50 tons per day. The hydro-electric power plant on Eagle river, which will supply power for operation of the Virtue mine and mill, will be in commission before October 1. It is planned to operate the mine and 20-stamp mill as soon as power is available. Full motor equipment for operating has already been received by the mining company.

Baker, July 20.

#### UTAH

##### SALT LAKE COUNTY

The production of the Utah Copper Co. for the first six months of 1912 was 53,300,000 lb. of copper as compared with 45,766,000 for a similar period in 1911, and 43,645,000 in the first half of 1910. The Utah Consolidated Mining Co. shipped 100,808 tons of copper ore and 8025 tons of lead ore in the first six months of the year. The estimated net earnings for this period were \$300,000. Development work slightly increased the tonnage of lead ore in the reserves, while the reserve of copper ore was maintained.

##### SUMMIT COUNTY

A decision has recently been rendered in the suit brought by the Conkling Mining Co. against the Silver King Coalition Mines Co. in favor of the defendant. The case was instituted in February 1908, when the plaintiff filed a bill in equity for title to a strip of ground, 135 ft. wide, on the western end of the Conkling claim, and by stipulation it was first determined to establish the title to this territory. If the Conkling company succeeded in establishing a title to this ground, then an accounting of the ores contained and extracted therefrom by the defendant company would have been ordered by the court, the plaintiff setting forth that ores to the value of \$2,000,000 had been extracted by

the defendant company. Two defenses were set up by the Silver King Coalition Mines Co., the first being that the 135-ft. strip was not part and parcel of the Conkling claim, and if it were a part of the same the plaintiff had no right or title to the ores contained therein for the reason that the apex of the Crescent fissure vein, in which the ores occur, was in the Monroe Doctrine, Cumberland, and the Constitution claims, which were and are owned by the Silver King Coalition Mines Co. This decision is important, as it releases for prospecting and development by the Coalition company a large area of virgin ground in the Crescent vein.

## WASHINGTON

### STEVENS COUNTY

(Special Correspondence.)—A company recently organized in Spokane under the name of the American Tungsten Consolidated Corporation, controls through options the main tungsten properties in eastern Washington. The directorate will be largely composed of Spokane capitalists, and W. Scheck will represent the German capital invested and will act as manager for the company.

Spokane, July 22.

The next meeting of the Spokane local section of the A. I. M. E. will be held at Republic, July 26 to 28. The Wallace, Idaho, meeting proved a great success, and the mine owners and Commercial Club members of Republic, who have extended a cordial invitation to the members of the Institute, hope to make this meeting equally profitable.

## CANADA

### BRITISH COLUMBIA

Forty engineering crews, consisting of 800 men with teams and pack-horses, will be sent into the field from Edmonton to make preliminary surveys for the Northern Territorial Railway Co.'s line from Edmonton to tide-water at Fort Churchill on Hudson's bay. This is to be part of a system of 1450 miles, from the Hudson's Bay country to Port Essington on the Pacific coast, connecting Edmonton with Lac La Biche, Fort McMurray, and Lake Athabasca. Plans are under way to begin grading work early next season, when the laying of rails will also be carried on, and in two years, according to present calculations, the line is to be in operation from Edmonton to the shore of Lake Athabasca, opening to commercial development the vast mineral and timber wealth of Alberta's farthest north. The company will then proceed with the construction of the line in the province of Saskatchewan. The Edmonton cut-off will be built later. The line from Lake Athabasca westerly will tap the rich agricultural resources of the newest north, continuing thence to the Pacific coast.

The first lot of copper ore from the Red Cliff mine, amounting to 700 tons, has been shipped to the Ladysmith smelter. A stock of several thousand tons of ore will be accumulated there before blowing in the furnaces.

### YUKON

A reduction in freight rates amounting to 10% has been announced by the White Pass & Yukon road, applying on mining machinery, fuel oil, dredge timbers, and other materials, from Skagway to Dawson. There has been recently an active discussion of freight rates, and it was announced that the closing of the Big Thing copper mine near Caribou was due to unsatisfactory rates. O. L. Dickeson, president of the road, has replied in an open letter showing that a reduction of 53% was voluntarily made on outgoing shipments, and that a similar reduction on incoming material, if made, would result in only a small saving to the mining company. It is also shown that rates are low as compared with those elsewhere. The rate on ore of the same grade from the Coeur d'Alene district to Tacoma, 431 miles, for example, is quoted as the same as the White Pass rate for 1000 miles.

## COSTA RICA

(Special Correspondence.)—The Aguacate Mines will increase the capacity of the plant from 50 to 100 tons per

day. The old crusher plant consisted of ten 1300-lb. stamps. The new crusher section is completed, and all the tanks for the cyanide plant have arrived. Construction will not be pushed until the end of the rainy season in December. Negotiations are under way for the delivery of 200 hp. by the first of 1913, after which the local hydro-electric plant will be closed. Where the new plant is being built it is possible to develop 900 hp. and deliver it at the mine by a transmission line 12 miles long. In the mine the lower or seventh level, which is 220 ft. below the present workings, is expected to reach the vein soon after the first of the year. This adit is being driven large enough for electric haulage. Development is now being carried on at the fourth and fifth levels. The stopes on the fifth level are at present supplying all the ore for the mill. The average value of the ore milled in June was \$16.58 per ton.

San Mateo, July 7.

## MEXICO

### CHIHUAHUA

(Special Correspondence.)—In the Parral district mail and freight service has been resumed, and supplies have

MAP OF CHIHUAHUA, MEXICO.

been received by the mining companies. The El Rayo M. & D. Co., the Alvarado M. & M. Co., and the Minas Tecolotes y Anexas continued operations in spite of the revolution, but other properties shut down, and in the Guadalupe y Calvo district all the mines were closed. The El Rayo company has 400 tons of concentrate stored which will now be shipped for smelting. Passenger travel in Chihuahua is difficult, owing to the torn-up condition of the Mexican Central railroad. The Mexican Northwestern is running a passenger train daily as far south as Madera. Santa Barbara, July 18.

The plant of the Dolores Mines Co. was recently attacked by a band of rebels, under the belief that the Federal garrison of Dolores was in the pay of the American mining company. The plant was gutted by fire with a damage of \$5000.

### SONORA

The Greene-Cananea Copper Co. reports for the month of June an output of 4,310,000 lb. of copper, 102,980 oz. of silver, and 533 oz. of gold. For the first half-year the copper output aggregated 22,898,000 lb., as compared with 22,220,000 lb. in the same period of 1911, while the silver output was 682,000 oz. and the gold 3372 ounces.

## Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

C. M. EYE has gone to Chihuahua.  
JOHN COSGRO has been in El Paso.  
C. C. BROADWATER has gone to New York.  
A. BURNER was at Libby, Montana, recently.  
FRANKLIN LEONARD, JR., is at the St. Francis.  
C. F. TOLMAN, Jr., will be in San Francisco next week.  
R. S. BOTSFORD has left London for the Ural mountains.  
MORRISON B. YUNG sailed for Hankow, China, on July 12.  
DONALD F. IRVIN is at Pasadena, California, on a holiday trip.

H. C. BELLINGER is returning to America by way of London.

R. B. MCGINNIS has returned from a professional trip to Oregon.

R. E. CRANSTON has returned to San Francisco from Yuba county.

C. GODFREY GUNTHER was in Oregon and California during the week.

F. G. BARAGWANATH is now with the Morococha Mining Co., Morococha, Peru.

R. B. LAMB sailed by the *Laurentic* for London, July 20, to be gone about a month.

RICHARD B. STANFORD arrived at New Orleans from Spanish Honduras this week.

W. G. SHARO, LEWIS A. MERRILL, G. W. METCALFE, and C. B. SPRAGUE are in San Francisco.

EDWIN J. COLLINS has returned to Duluth from professional work in Fremont county, Wyoming.

H. A. BRANDT is now in charge of the British Columbia Copper Co.'s Lone Star mine, at Danville, Washington.

E. D. LACHMAN, formerly store manager for the Dolores Mines Co., has resigned and is now at El Paso, Texas.

H. RIES is in British Columbia investigating the clays of western Canada, and plans to be in San Francisco early in September.

A. G. KEILLER has been appointed mill superintendent at the Aguacate mines of Costa Rica, in charge of operation and new construction.

SPANGLER RICKER has resigned from the Mazapil Copper Co. and is now with the Santa Rosa Mining Co., Ltd., at Concepcion del Oro, Zacatecas, Mexico.

D. FORD McCORMICK, formerly with the Socorro mines, Mogollon, New Mexico, has accepted the position of engineer for the Aguacate mines of Costa Rica.

ROBERT LINKLATER, employed in the construction of the mill for the Aguacate mines, is in the United States on a vacation, but will return to erect the 10-stamp mill for the Porvenir Mining Co., of Costa Rica.

H. E. OLUND has resigned his position as general superintendent for the Lake Superior & Nevada Development Co. and engaged in consulting engineering work as a member of the W. O. N. Engineering Co., at 626 San Fernando building, Los Angeles.

## Obituary

WALTER GLOVER was killed by a switching engine at the Cerro de Pasco smelter, June 17. He had been in the employ of the company for three years.

W. A. NEVILLS died in San Francisco on July 11. He was born in London, Ontario, about 80 years ago, and has been a well known figure in Tuolumne county mining for over twenty years.

## Market Reports

### LOCAL METAL PRICES

San Francisco July 25.

Antimony.....	11-11½c	Quicksilver (flask).....	43
Electrolytic Copper.....	17½-18c	Tin.....	60-61½c
Pig Lead.....	5.00-5.35c	Spelter.....	8-8½c
Zinc dust, 1400 lb. casks, per 100 lb., small lots \$9.50-9.75; large \$7.50-8.50			

### METAL PRICES

(By wire from New York.)

NEW YORK, July 25.—Copper is now strong and advancing in price. Lead remains quiet, and spelter firm.

Average daily prices for the past week, in cents per pound, based on wholesale transactions, standard brands, are given below.

Date.	Electrolytic Copper.	Lead.	Spelter.	Silver, per oz.
July 18.....	17.05	4.75	7.18	60½
" 19.....	17.15	4.73	7.18	60½
" 20.....	17.15	4.73	7.18	60½
" 21.....	Sunday.	No market.		
" 22.....	17.33	4.73	7.18	60½
" 23.....	17.48	4.73	7.18	60½
" 24.....	17.48	4.73	7.18	60½

## The Saurer Truck at Plumed Knight Mine

By H. T. McDONALD

On January 13, 1912, I started from New York for Tucson, Arizona, to make a 90-day test with a 6½-ton Saurer truck in hauling ore for the Pioneer Smelting Co. The truck had been shipped about 10 days before the start and was delayed, as usual, in transit. I waited four days for its arrival, and put in the time to good advantage looking over the roads and making suggestions as to their improvement. The truck arrived on January 21 and was immediately unloaded and found to be in good order. I drove it to a garage and had it supplied with oil and gasoline and made ready for an early start the next day. The truck created quite a sensation in town, and I had to listen to much comment and criticism, some of which I shall repeat.

While every one admired the sturdy construction, and said it "looked like a real truck," few had anything good to say about auto trucks. One wiseacre said, "Huh, here's another of these failures; this truck will go the way of the rest that came here." Another one said: "That's right, this part of the country is a graveyard for these things. You'll never do anything with that." Still another said: "So you think you can haul 6½ tons with that engine. Why, a big traction engine failed to pull a pound on the same road as you are going on, and several other autos fell down here in the last two years. You'll have to leave that in the junk-shop with the rest of the trucks." All this was very soothing to my nerves, but I said nothing, and was mighty glad to find the garage I had been looking for.

I left Tucson at 9:35 a.m., after doing some shopping with A. L. Waters of the Pioneer Smelting Co., and started for Camp Corwin at Shawita, about 22 miles south of Tucson.

Several more wise ones said I would have all I could do to reach Shawita, and as I traveled along I found that road conditions were all my informants had claimed and then some more. Mr. Waters led the way in his Overland and watched the performance of the truck when going thorough the several bad 'sand washes.' A 'sand wash' is a sort of dry river bed, which in the rainy season carries a tremendous volume of water. The roads cross these 'washes' at the best part, but still there is always new sand at a depth of from 4 in. to 2 ft. The truck crossed these 'washes' with no trouble whatever, and its stock went up a notch or two. Camp Corwin was reached at 12:10. After dinner and a critical inspection of the truck by the company officials, I started for the Plumed Knight mine, 8 miles west of Camp Corwin. The roads, if I may call them such, began to grow worse, and I had my doubts as to ever hauling over three tons at any time. 'Sand washes' were numerous on this 8-mile trip, and were crossed with much difficulty. After hauling the first load of 3½ tons to try out the road and truck, I decided that the roads would have to be improved considerably before 6½ tons could be hauled, so a force of ten Mexicans was put at work, under my direction, to do some road building.

I kept on hauling small loads and kept my eye on a road gang. The sand washes were corduroyed, waste material from the mine was laid on top of that, and thus a fairly good road was started. I then began to increase the weight of loads, and by February 1 was hauling 6½ tons and making four trips daily. No trouble was experienced with the truck mechanically, but owing to the poor quality of the lubricating oil the valves would stick because the oil gummed. The gasoline also had much water in it. I drained a water-glass full about every other day from the trap and carburetor. As gasoline costs 22c. per gallon there, the superintendent said the water thus obtained could be pumped for less than that. Owing to the altitude (nearly 5000 ft.), a little difficulty was found in getting the carburetor adjusted so as to get the maximum mileage, but I soon found the proper combination

and increased the mileage from 3 per gallon to 4.9 per gallon, which I found was the best that could be done, owing to the large amount of low-gear travel that was done. Several grades in the first  $2\frac{1}{2}$  miles from the mine were from 8 to 20% and required one-half hour to make the distance; the remaining  $5\frac{1}{2}$  miles was a steady descent of about 2 or 3% over sand road and was covered in about 25 minutes.

A road scraper of wood and steel had been made for me, and it was hauled over the roads about twice a week. I soon found this too heavy to haul with a load, so it was abandoned and a new one made of two pieces of steel rail. This proved to be very successful, owing to its extremely sharp cutting edges and lightness, and in the course of a couple of weeks a nearly perfect road resulted, considering its sandy character and lack of foundation. The first month's hauling was not a very good showing, owing to the small loads and the time spent in fixing the road, and cost over \$1 per ton to haul. The second month's hauling came below 90c., and the third ran down to 71.7c. per ton, as a double shift of drivers was put on and the haul increased from 24 to 41 tons per day. At the beginning of the last thirty days of the test I had the truck doing 96 miles per day on 18 or 19 gallons of gasoline and one gallon of lubricating oil. At the end of the last thirty days, April 22, our 'stand-up' qualities showed up so plainly that the trucks were accepted. I agreed to stay until May 1 to put the finishing touches to the drivers I had been instructing. The truck was equipped with Goodrich 'Wireless' tires that covered more than 7000 miles and were good for at least 3000 more. Upon being measured they were found to have worn about  $\frac{1}{8}$  in. per 1000 miles. Considering the very sharp stones in the road and the high temperature to be found there, I believe this to be remarkable.

### Simplex Rivetless Chain

This chain was recently patented by Joseph L. Lee, general superintendent of the Cross Engineering Co., Carbon-dale, Pennsylvania, and manufacturing and selling arrangements have been entered into with the company, which is preparing to market the chain at an early date. The principle of this chain is entirely new, but simple, from which

it derives its trade name of 'Simplex.' The accompanying illustrations of links, pins, attachments, and assembled parts are to a large extent self-explanatory, but the following claims are made for this new product by the inventor and manufacturers:

This chain is interchangeable in all parts. Its parts are easily and quickly detachable, and each section can be so detached in less than a minute. The links can be released or removed by a horizontal movement of the diameter of the pin, or in the 9-in. pitch,  $1\frac{1}{8}$ -in. movement,

doing away with the necessity of adjustment of take-up when links or pins require renewal, or to reverse the pins for further service. It will operate over either a sprocket wheel or a traction wheel by reason of the concave shape of the links, and is also interchangeable with certain other types of rivetless chain. The chain has a wearing surface on both link and pin equivalent to standard riveted eye-bar chain, generally known as the 'Scranton' type of chain, the pins being reversible, so that after becoming worn on one side they can be reversed  $180^\circ$ , so presenting the unworn side for 100% additional service, and at the same time nearly restoring the chain to its original pitch.

A special feature of this chain, as well as a distinct advantage over any other type of chain, is the 'lip' shown on the outside links. When the chain is in working position, and whether in the position of passing over a sprocket or traction wheel, the double-slot space back of the pins on the centre links, forming a recess or pocket, is entirely closed. This prevents dirt or gritty material from coming in contact with the wearing surfaces, and if desired the recess or pocket may be filled with any solid lubricant, such as graphite or hard grease, and so insure the longest possible life to both link and pin at the contact points of wear and friction.

The links, being solid, have a distinct advantage over the web, or open, type of link, as there is no compression at any point on either link or pin to cause the chain parts or attachments to stick or to be disconnected with difficulty, and it is not necessary to remove the attachments to disconnect the links or pins.

The two centre links form a pocket for the insertion of the several forms of attachments required, and may be reversed 'back to back' and so used for attachments requiring side elevation or conveyance. Attachments for this chain will first be made of malleable iron to meet standard elevating and conveying requirements, and for extraordinary service certain attachments will later be made of a special tough steel. Attachments when bolted to links will, it is claimed, bear an equivalent strain as if cast in one piece. The links are to be drop-forged from 30 to 40-point carbon steel and broached to assemble to accurate pitch, and the pins are also to be drop-forged and machine-finished, and to be shop-assembled to links to insure the free working of chain parts.

It is the claim of the manufacturer that this chain will in a large measure displace several of the types of riveted chain now in use. The Cross Engineering Co. is preparing to manufacture this chain in 4-in., 6-in., and 9-in. pitch, and it is stated that the chain will be sold at no general increase in price over the standard type of drop-forged, riveted bar chain. It is the general claim that Simplex rivetless chain is more simple to assemble and disconnect than any other type of rivetless chain now in use, and that it is as easily detached as the Ewart type of detachable chain or belting.

### Commercial Paragraphs

The KEYSTONE DRILLER Co. has opened an office at 1629 Candler building, Atlanta, Georgia.

MARTIN SCHWERIN & Co. have opened an office at 25 Broad street, New York, as consulting engineers.

The LIMA LOCOMOTIVE & MACHINE Co. has been succeeded by a new company called the Lima Locomotive Corporation. Increased capital has been provided and the plant will be enlarged to handle from 900 to 1000 locomotives per year. Four thousand men will be employed.

The DENVER QUARTZ MILL & CRUSHER Co., of Denver, Colorado, reports the following recent sales: One 50-ton plant to A. A. Taubeneck, Greenville, California; one 50-ton plant to Weaver Bros., Salina, Colorado; one 100-ton plant to Thomas B. Everett, Paramaribo, Dutch Guiana, South America. The above plants are to work on free-milling gold ore.

## EDITORIAL

**P**ETROLEUM production in California seems likely to establish another record this year, the output for the first six months indicating a probable total for the year of 87,000,000 barrels. This is all the more striking in that no phenomenal gushers have swelled the output this year.

**P**RE-CAMBRIAN rocks are great storehouses of the metals, and a knowledge of their distribution has helped to the discovery of many an orebody. Mr. M. K. Rodgers has compiled a general map of North America, based largely on the work of Messrs. C. R. Van Hise and C. K. Leith, and showing in black and white the principal areas of these rocks.

**B**RAZIL is attracting unusual attention in the United States at present. Development of the great iron ore deposits in Minas Geraes, in which American companies are taking active part, has called attention to the possibility of developing mines of other minerals. Messrs. J. E. Bundy, Charles Beun, and S. D. Horton, experienced California prospectors, are planning to leave New York the last of August for a prospecting trip through western Brazil. A large and well equipped expedition will also leave September 5 to thoroughly test reported gold-dredging ground in the state of Goyaz, and still other things are in prospect. We published, November 4, an excellent general account of Brazil as a field for the prospector, written by Mr. A. P. Rogers, on his return from an eight months stay in the western part of the country.

**C**ANAL tolls are being vigorously discussed at Washington. We are old-fashioned enough to believe best results will be obtained if the canal be run on the most businesslike basis. Tolls that will cover operating charges and at least contribute toward interest charges would still be sufficiently low to attract foreign traffic to Panama and allow competition with Suez. Coastwise traffic is already thoroughly protected against competition in that none but American vessels can take part. If it be desired to protect the ships against the railroads the logical means is through control of rates, exercised by the Interstate Commerce Commission. If, on the other hand, the real object is to subsidize American ships it would be more honest to vote a subsidy bill than to jeopardize good relations abroad by sharp practice.

**D**EATH of the Emperor of Japan removes one of the real and powerful influences for progress in the Sunrise Empire. In a land where the ruler is regarded not only as the political sovereign of the people, but as the heaven-descended head of one big family, his influence is far beyond that had by any Western ruler. The phrase, 'for the honor of the Emperor,' is no empty form, but marks a real and reverent feeling common to all Japanese. Mutsuhito, the one hundred and twenty-first Emperor, was a worthy descendant of the line which has certainly reigned since about the time the Goths thundered at the gates of Rome, and which, according to Japanese chronology, began with Jimmu Tenno in 660 B.C. Born in 1852 and

reared in the seclusion of the old palace at Kyoto, he was but 15 years old when he succeeded to the throne and, with the resignation of the Shogun, faced larger responsibilities than had any immediate ancestor. He played his part well, and to the fact that he devoted himself with discretion and wisdom to the modernization of his people, we owe the new Japan. A few mistakes on his part might well have given us instead another Korea or Siam. It was not that he did not have and follow great ministers, but that he used his influence always on the right side. In the critical conditions incident to the substitution of the modern competitive system for the ancient paternal feudalism, men bore their trials gladly and sacrificed place and fortune 'for the honor of the Emperor.' He guided his people well and the world is much in his debt.

**T**AMPING drill-holes is common where black powder or other low explosives are used, but with dynamite in rock there has been much dispute as to the need and value of tamping. The United States Bureau of Mines has recently studied the subject and presented its results in Technical Paper 17, written by Mr. Walter O. Snelling and Mr. Clarence Hall. Experiments were carried on by exploding shots in a homogeneous material with and without tamping, and measuring the expansion produced. The results were favorable to tamping. Incidentally it is worth recalling that the introduction of tamping charges in the Treadwell mines, on the advice of Mr. Snelling, resulted in a large saving in explosives. Studies of these and similar questions by the Bureau are yielding results of large importance to miners.

**H**AVING taken occasion in the past to criticize delay in the United States Geological Survey in issuing statistics, we have especial pleasure in commending the work now being done by that organization. We reprint this week figures of spelter production and consumption for the first six months of the year. These are not merely interesting in themselves, but are especially valuable in that they are the only complete figures available. The copper producers have their own statistical bureau, and the ore production at Joplin and in Wisconsin is published weekly, but hitherto it has only been possible once a year to know what the lead and zinc furnaces had been doing. Mid-year figures for spelter are good. We hope the Survey officials may find it possible to extend their work to cover quarterly or even monthly figures for both zinc and lead.

**L**AND laws in the United States have been novel in many particulars, and there is a widespread feeling that the times demand their general revision. Preliminary to the making of any recommendations the committee on revision of the mining law, appointed by the Mining and Metallurgical Society, has been compiling the opinions and criticisms of those competent to judge the matter. Under the active leadership of Mr. H. V. Winchell a large amount of valuable data has already been collected. Elsewhere we publish a particularly informing letter on the subject written by Mr. A. Montgomery, the accomplished State Mining Engineer for Western Australia. Such a thoughtful contribution from the outside should be especially helpful. "To see ourselves as others see us," should indeed "frae monie a blunder free us, and foolish notion."

**C**OMPARISONS are always worth reading when made by a competent observer, and those of Mr. F. V. Stanley Low of mining practices in the United States, Australia, and Cornwall, published in *The Mining Magazine* for July are quite worth while. Although admitting that exact comparisons are impossible owing to different

conditions involving the practice, Mr. Low has noted certain strong characteristics of each district visited which gave an individuality to their work. Mining in America has in many instances developed in a one-sided manner, and this may partly account for the results noted. However, with the single aim of obtaining the maximum profit for operations, naturally similar results have been reached in widely distant districts. The most impressive feature of American practice seems to have been the magnitude and organization of the operations, while in the Kalgoorlie and Broken Hill districts of Australia the excellence of 'work-effort' is notable. Cornwall, which has produced so many mines for other districts, seems to have lagged behind and to be addicted to obsolete and inefficient methods of mining.

**G**RADUATE work in engineering is to be a specialty of the University of Illinois, according to a recently issued bulletin. Practicing engineers will not be apt to take exception to the view that engineering, in developing, becomes more scientific, and that specially trained and prepared men will be required to successfully meet new problems which arise in old professions. There is no question as to the need, but the University will have to prove by the result of research work done, or by the high quality of the men trained in the laboratories, that it is prepared to fully meet this need. A graduate school of engineers is probably the dream of every engineering instructor, but even the boldest must have some question as to methods to be tried and results to be sought. The best field for the professional schools has been in supplying students with the essential fundamental knowledge, underlying the various professions, and a training which has given them confidence in meeting new difficulties. The University can supply the working tools and sometimes the inspiration, but the graduates must do their own building outside the supporting arms of their alma mater. For this reason there must be some question as to the probable success of any university which attempts to give its recent graduates a comprehensive enough view of the future of engineering to enable them to work to advantage in research. A man must usually find his own problems before he can attempt to solve them, and these problems are easiest to find in actual practice. The university which best equips its student to solve problems outside the walls of its own buildings is best maintaining 'graduate work in engineering.'

**T**EN YEARS ago no reputable engineer would have thought of estimating ore reserves in terms of 'millions of tons.' Outside of the elaborately worded prospectus designed to sell stock in Western bonanzas to New England school teachers, the phrase was unknown. So fast has our education progressed, however, under the influence of the bulletins of the low-grade 'porphyry copper' companies, that little comment is excited when an official announcement is made of an orebody with a tonnage estimated in seven or eight figures. The Braden Copper Company, which in April 1911 reported a modest 12,000,000 tons as the amount of its ore reserves, now finds that this was a conservative estimate, and that 23,000,000 tons is developed, with a chance for still further increase. To the shareholders this is undoubtedly gratifying information, but before engineers at large the question will arise, "What is to be the policy of the company in handling this ore? Will the management be content to effect a recovery of 60% of the metallic contents, on the ground that copper is the cheapest thing it has, crowding the production to take advantage of a favorable market, or will it work slowly toward an increased saving by careful tests and trials of new methods?" According to press dispatches, the flotation process of the Minerals Separation Limited of London, and the leaching

of concentrate will both be tried. The outcome of these experiments will certainly be watched with interest by engineers and with hopes for success. It may not be an acceptable commercial attitude, but there are engineers who believe that a company possessed of enormous resources, owes something to the public beyond the mere production of rapid dividends. The exhaustion of a part of a country's resources should be attended with the least possible waste, and with some contribution toward the advancement of the industry which handles the material produced.

OUR esteemed, so to speak, contemporary, the *San Francisco Chronicle*, has been indulging in an orgy of figures in discussing the Alaska Juneau mine. The latter contains, undoubtedly, a large orebody, and by careful work it may be made a valuable one, but the most sanguine of its owners hardly expects "\$4,000,000 per year for 200 years," and we are forced to believe someone slipped in a few extra ciphers. As a matter of fact, Mr. F. W. Bradley and his associates are planning now to treat 25,000 tons of ore per month, and hope by careful sorting to keep the grade of the ore up to \$2 per ton. Up to now the mine has been worked on a small scale only, by open pit and with 40 stamps. The average grade of the ore has been about \$1.60 per ton and the cost \$1.10. This performance, we think, is more remarkable even than the admittedly large size of the deposit. It is relatively easy, in the case of large orebodies, to obtain low costs when working steadily with large and expensive equipment, but to obtain minimum costs with a 40-stamp mill operating only in the summer, is the acme of good work. Under the peculiar conditions at Juneau these costs would undoubtedly have been increased if mining had been attempted upon a large scale, and to make a success of the enterprise under way it was necessary to so mine and sort as to raise the grade. The careful studies of this phase of the problem were quite as necessary to success as the planning for the new mill and workings. Incidentally, the new workings involve some interesting features. The old open pit is to be tapped by a 900-foot raise from a 7000-foot adit now being driven, and from the mouth of the latter a flume and tramway will be carried around the edge of the mountains to about 500 feet above the mill, which has been built on the shore below Juneau to avoid the snow at the mine. Water from the Silver Bow basin will be piped down through the raise and used to generate power in the mine. At the mouth of the adit the flow will be joined by the additional stream won last summer, and at the mill there will be another drop and power station. The whole plan has been carefully devised and the enterprise is an excellent example of how constructive imagination reinforces experience in development of modern industry.

### Management of the Institute

Mistakes are less interesting than plans, and for our part, in considering the affairs of the American Institute of Mining Engineers, we are more concerned with the future than the past. Such errors of judgment as have occurred have been few and relatively unimportant, and blame may well be shared equally by officers and members. A more general assumption by the members of responsibility for the conduct of the Institute would have precluded the overconcentration of power which seems at the bottom of the present trouble. If responsibility is left to an officer the power must go with it, and those who shirk have little right to complain.

Among the recommendations of the Committee of Five, the one which appeals to us as of first importance is for a reorganization of the business of the Institute so as to prevent for the future a 'one man' management. The

Council and the Directors, acting together, should be the real centre of authority. Men are elected to these boards as trustees for their fellow members, and should not accept the position unless prepared to give time and thought to the work of the Institute. Service rather than money is needed. It has too often happened in the past that officers, finding themselves unable to devote time to the Institute, have contributed instead money to the land fund. There is nothing so dangerous as an 'ornamental' trustee, and that he is at the same time generous makes the matter no better. The members, having voted to accept the Carnegie building, should not be relieved from responsibility for paying for the land, and, on the other hand, the Directors and Councilors are trustees for funds belonging, not to the officers, but to the members. In many cases payment of the annual dues involves real sacrifice on the part of beginners in the profession and even of older men when out of work. This position of trusteeship should be kept in mind, but, with the large membership in the Institute, there should be no difficulty in selecting always an active and able body of trustees.

In considering the routine management it should be remembered that there are two things to be taken into account. The Institute is a social-technical society, and it is also a publishing house. Examination of the figures compiled by the Committee of Five shows that the actual income from members is now less than in 1906, while the expenses have steadily increased. That the business affairs have not become hopelessly involved has been due to increased profits from the publishing end of the business. In other words, the advertisers in the *Bulletin* are footing the bills. Whatever questions there may have been originally as to the wisdom of the Institute embarking upon publication in a competitive field, it has already been done. Speaking for one publishing house in this same field, we can only say that we extend it a hearty welcome. Publishing, however, is a business, and its proper conduct requires a trained business manager. The secretary of the Institute is, and should be, mainly concerned with other matters. His training and outlook should be that of an editor rather than of a publisher, and an excellent secretary may well be a poor business man. Indeed, the better he fills the one place, the less desirable it is that he should be charged with duties belonging to the other. There should, therefore, be two chief officers in the permanent force, a secretary and a business manager. Toward the salary of the latter may be applied the commissions now paid on advertising, since the size of the business is not, as yet, too large to prevent one man doing the soliciting and also handling the office. If he takes entire charge, under an executive committee, of the business of the Institute, the secretary will then have the time to do his proper work in building up the membership and sustaining the Transactions on the high plane set by Dr. Raymond.

Mention of the latter brings up another point upon which a word is due. The Directors, it now seems, find that there was no legal authority for creation of the position of secretary emeritus when Dr. Raymond retired from the secretaryship, and that formal action of the members will be necessary to carry out their intention. In the meantime Dr. Raymond has been appointed special editor. We are sure that the members will vote unanimously for any amendment necessary to show their appreciation of the long and faithful service of the ex-secretary and to provide for such continued connection with the work of the Institute as his strength will allow and the funds available will permit. The members have a lively appreciation of what Dr. Raymond has done for the Institute and will wish to do everything possible to express that feeling.

## Modern Methods of Gravel Excavation

By FRANCIS J. DENNIS

Having had occasion recently to attempt to find some method for removing the overburden of barren gravel from a strip of 'pay' gravel, which it was planned to subsequently mine by small steam-shovels and by hand, I was impressed anew with the difficulties in such a situation. In the particular instance in view, placer work, the gold was so distributed and the character of the bedrock was such that it was not feasible to dredge the ground. The width of the 'pay' channel was from 100 to 200 ft., and the thickness of the overburden from 12 to 20 ft. The surface for a considerable distance on either side of the 'pay' channel was practically level with the surface of the overburden of the channel. It was desirable to avoid the use of cars or wagons in disposing of the spoil from the stripping process. The character of the gravel ranged from fine gravel, sand, clay, and mud up to boulders of from 18 to 20 inches in diameter; in fact, the characteristic gravel usually found in the ordinary river bed. The problem was first to find an efficient method of disposing of the spoil on the banks on either side and still permit access to the pit, so as to mine the 'pay' gravel below. The steam-shovel naturally suggested itself as the most efficient digger, but the average steam-shovel has a very short digging radius and an even more limited stacking radius. Either some other form of digger capable of excavating gravel of the character described and also capable of stacking the large amount of spoil to be handled, had to be found, or some means provided for taking and stacking the spoil from the steam-shovel. Any machine or machines chosen had to be such as could be readily moved forward as the work advanced along the channel. To find the most efficient machine, a trip was made to various points in the country where aqueducts and canals are being constructed and coal and iron-ore stripping is going on.

Various methods of digging and stacking the spoil were found to be in use, and about as many different opinions as to the best machine for the purpose as there were machines in use. The shallow canal usually constructed for carrying water for irrigation or for drainage purposes is a comparatively simple problem. The canal dredge, the steam-shovel, the drag-line bucket, and the clam-shell are all being used in digging it. The disposition of the spoil on either side of the cut is a simple problem; it is a question of getting the most efficient digging machine to meet the local conditions. But where the cut is comparatively wide and deep and the amount of spoil large, and especially where it is desirable to leave a fairly wide berm between the edge of the cut and the spoil-bank, the question of handling the spoil becomes serious. To get a machine or machines that will dig and stack efficiently, and yet be capable of being easily moved ahead as the work advances is a problem that has led to various types of installations. In some cases where coal and iron-ore stripping and mining is in progress, the large revolving steam-shovel with a very long boom has been found quite efficient machines. These shovels are capable of making a comparatively wide cut, 40 ft. or more at the bottom, and of stacking this overburden on the bank of the cut so that the coal or iron under the overburden can be readily mined; one handling only being necessary in order to give access to the coal or iron. I witnessed instances where this was successfully carried out, where the overburden was 22 ft. thick. Where the overburden is very thick, the width of the cut is necessarily narrow. Of course, the character of the overburden, especially whether or not it can be taken out and leave the walls of the cut fairly steep, has much to do with the success of this method of mining. The width of the bottom of the cut is the important point. It is not only a question of yardage excavated, but of coal or iron exposed by the operations, and

where the overburden is of such a character that the sides of the cut would naturally take on a decided slope, this method of mining would be impracticable, the shovel being unable to stack the spoil. The material overlying the coal and iron at the points visited stood up well, leaving the sides of the cuts very steep. Where the cut was deepest it was sometimes found necessary to use the dipper and dipper-handle and crowding engines to push back the top of the spoil-bank in order to enable the shovel to stack all the overburden. This retarded the speed at which the shovels dug, but the small percentage of delay caused was of little importance when it is considered that only one handling was necessary to uncover the coal or iron. The swing of a long boom also necessarily consumes more time than would that of a short one, but these large shovels dig and make the swing surprisingly fast. A good operator will dig and stack from 40 to 60 loads per hour, and as a dipper carries  $3\frac{1}{2}$  cu. yd., the capacity of one of these large shovels is considerable. One of these shovels will dig and stack from 120 to 200 cu. yd. per hour. They are capable of digging very hard material, but this necessarily consumes more time, and where this condition exists it pays to keep a couple of men in advance of the shovel with steam or air drills, putting down holes and loosening up the ground by blasting.

It is not proposed to describe in detail these big shovels, but merely to state what I found them capable of doing. However, a few general statements in regard to the construction of these big shovels might not be amiss. The lower frame is of steel, mounted on four swiveling trucks with four double-flange wheels on each truck. To the top of this frame is fastened a rail circle and cast-steel circular rack for rotating the machine. A hydraulic equalizing device is provided, so that the machine can be moved ahead and operated on uneven tracks without twisting the frame through the unequal distribution of weight, and to keep the turntable on a level so that it is capable of revolving without unnecessary strain and with a minimum application of power. The machines are self-propelling. Three men are required on one of these large machines, and four more to lay tracks and prepare for moving ahead. These machines have 65-ft. booms and  $3\frac{1}{2}$ -yd. dippers, and are capable of doing the work above indicated. Larger shovels with 90-ft. booms, 6-yd. dippers, and weighing about 200 tons are now being built. These new shovels should stack to a height of about 62 ft. above rail (boom at  $45^\circ$ ) with a radius of cut at the bottom of the pit of 61 ft., and should have a capacity of from 150 to 300 yd. per hour. These larger shovels will handle a depth of overburden with which the present shovels are unable to cope, to say nothing of taking a much wider cut, and should open new fields to stripping operations. The shovels make one cut to the limits to be worked, the stripped material is removed, and the shovel returns on another cut, depositing the overburden in the open space. This permits of a wider cut on the second trip, the shovel not having to stack so high, and as the swing is less, the capacity is greater. It must always be borne in mind, however, that the use of the long-boom steam-shovel for stripping operations and the disposal of the spoil in one handling, providing that any considerable depth of overburden is to be handled, is limited in its application to ground where the sides of the cut will stand fairly steep. Where the ground is soft and the banks take a decided slope, it is difficult to strip any considerable width so that the underlying material can be mined, even with a long-boom shovel. The short-boom shovels handle a greater number of dippers per hour, cost less, and consume less power. At the Chino Copper Co.'s property, in January 1912, a No. 1 Marion model 91, steam-shovel, with  $3\frac{1}{2}$ -yd. dipper, averaged 1721

yd. per shift and at the rate of 200.8 yd. per actual working hour. It is often desirable to use the smaller short-boom standard steam-shovels, the spoil being disposed of by a second handling. Cars and locomotives are generally used for this purpose, a dump being established at some distant point. But where it is desirable to stack the spoil on the immediate banks, and especially if a berm is to be left between the edge of the cut and the spoil bank, some form of crane, incline tippie, elevator, or conveyor must be provided.

The locomotive crane, traveling on rails along the berm as the shovel advances along the bottom of the cut, has been quite successfully used, the crane lifting and stacking the contents of a shallow box holding from 3 to 5 dipperfuls of material, another box being filled by the shovel while the crane is dumping one load and returning the 'empty.' The shovel may fill the box while placed either

the bottom being filled by the shovel while the other is ascending, dumping, and returning ready to take its load at the bottom. This apparatus is very expensive to construct, entails the laying of a double set of rails to advance it along the cut, and its use means that the shovel must revolve clear around to deliver its load into the cars, thus somewhat curtailing the capacity. However, this apparatus does seem to be able to keep a standard 1½-yd. shovel busy, and to be able to dispose of the spoil so that it will not come back into the cut. It seems out of the question to devise any method of disposing of the spoil on the immediate banks by a machine moving along the bottom of the cut, which would not entail the necessity of the shovel swinging clear around to deliver its load, as this second machine must necessarily be placed behind the shovel. Its cost of construction and the cost of laying tracks are its greatest drawbacks.

THEW SHORT-BOOM, TYPE A-1, STANDARD SHOVEL WITH CROWDING ACTION.

at the bottom of the cut or on the berm at the edge of the cut, but in no instance did I find an application of this system where a standard 1½-yd. steam-shovel was kept busy. The breaking of the bales on the boxes, and the difficulty of effecting a rapid detachment from the empty and attachment to the loaded box, cause a considerable loss of time. In some instances a double-boom crane is used, the booms being opposite each other, the crane making a half circle to each load, dumping, then continuing the circle to drop the empty box and pick up its full load. The double crane is very much more expensive, is a heavier machine to move forward, and it is doubtful if it does any more work.

Another device is a portable incline-tippie, moving along the bottom of the cut just back of the shovel, the upper end of the incline extending well over onto the bank of the cut, so that the spoil can be dumped from cars and stacked without flowing back into the cut. This incline has a double track and is provided with two cars, each capable of carrying from four to six dipperfuls of material. These cars are hoisted by a double-winding engine, each drum working independently, so that one car is at

In discussing the problem of disposal, I am assuming that a variable material irregular in size, varying from fine to coarse, is to be handled. The same conditions would obtain in dealing with the average river-bed gravel, and the question arose whether such a product could be delivered from the shovel to a belt-conveyor so mounted as to be readily advanced in conjunction with the shovel. Such a belt-conveyor suitably mounted would be much lighter than the incline tippie above described, would not entail the expensive track-laying, and would be much less expensive to construct and operate. To spill direct from the shovel on to the belt would be out of the question, and the only solution seemed to be to put in a hopper with some feeder to the belt which would give the latter a fairly regular and even load. I was able to find instances where this was being done with run-of-mine coal, but that is a very different material and easier to feed on to a belt than is river-bed gravel of the kind described. The device in use to keep the coal near the middle of the belt was a skirt-board just below a feeder, the skirt-board being given a slight movement which forced the coal toward the middle until it came to rest on the belt. No instance was

found where heavy material such as mixed gravel of the character described was being successfully fed to a belt-conveyor.

The drag-line bucket revolving machine is also largely used for excavating gravel and soil, and has won recognition as an efficient and economical digging and stacking machine. As a digger it is hardly as efficient as the steam-shovel, but as a stacker it has advantages over the latter. The first cost of a drag-line machine is much less than that of the long-boom revolving shovel, it is cheaper and easier to transport, it can be operated and moved ahead on wide wheels moving on planks, and it will handle a substantial yardage per hour. Buckets hung from chains and those having a fixed bale are both in use. The latter seems the much more efficient digger, but where the ground is soft or has been previously loosened, the former does good work. The bucket with the fixed bale will dig harder material and is easier to control and guide in a definite direction. The drag-line bucket with the fixed bale is doing excellent work in widening and deepening the New York barge canal. In this work it is necessary to leave a wide berm and to stack the spoil at a considerable distance from the edge of the cut. The digging is not difficult, clay and ordinary soil being handled by this method. The machines have long booms, are of the revolving type, have  $1\frac{1}{2}$ -cu. yd. buckets, and cut the soil and clay more readily than any other machine in use with the exception of the steam-shovel, and where the latter method is used, a second handling is necessary in order to dispose of the spoil. Even the very long boom steam-shovels previously mentioned in this article would be unable to dig and stack with one handling. These  $1\frac{1}{2}$ -cu. yd. drag-line machines dig and stack from 600 to 800 cu. yd., and sometimes even more, of this material in eight hours. The material is dug from the bottom and side of the canal and stacked to leave a berm about 20 ft. wide between the edge of the cut and the spoil heap. The cost of operation is not great; five men operate the machines, level ahead of the machine, and assist in moving along the berm after a portion of the spoil has been deposited thereon; it being necessary to raise the berm of the canal some three feet in order to conform with the conditions of the contract. The bucket is first used to roughly level the spoil deposited on the berm. The machine is moved ahead by gripping the bucket in the soil ahead of the machine and moving up under power of its engine. The laborers take the planks from behind the wheels and place them in front as the machine advances.

The clam-shell revolving derrick is also in use on this canal, but is a very inefficient digger and does not give satisfaction. The clam-shell bucket is useful in unloading coal and ore from barges, and in dredging mud from river bottoms and similar work, also for digging soft loamy material, but can hardly be classed as an efficient digger for the handling of the harder ground in place or for coarser gravels.

Cantilevers moved along the berm on wide tracks are also used in the canal work. One end of these cantilevers extends well out into the centre of the canal, and the other back from the edge to a point designed to be the apex of the spoil heap. Drag-line buckets are usually operated from these cantilevers, the machine being moved ahead as the work progresses. The time consumed to load the bucket, raise it, and pull it up along the cantilever to the dumping point, is considerable, and the capacity of the machine correspondingly small. It is no better digger than the ordinary long-boom, drag-line bucket, revolving machine. It is very much more expensive to construct, harder to move ahead, and does not allow the same flexibility in digging, the operation of the bucket being confined to a space directly in line with the cantilever. Furthermore, the machine cannot be used as a crane or for the various other purposes to which a drag-line boom machine can be put. It is a formidable and costly machine for the work which it accomplishes. At points along the canal where the cut is necessarily very deep, due to the

topography of the country, two handlings are necessary in order to dig the material and dispose of the spoil. A drag-line bucket would be too far away from the boom to do good work, and the time consumed in hoisting, swinging, dumping, and returning would curtail its capacity too much, while any steam-shovel built could not possibly stack on the sides, away from the edge of the cut. In such instances it has been found most economical to use the standard steam-shovel to dig the material, the spoil being deposited in large shallow boxes, carrying from four to six dipperfuls, which are raised and dumped by a locomotive traveling crane moving along the berm as the steam-shovel advances. Where rock work is encountered, holes are drilled and blasted to loosen the material before being attacked by the shovel. This method of second handling is not sufficiently efficient to keep a fair-sized steam-shovel busy, and the work is necessarily costly. Movable towers on either side of the cut, from which a 'flying-fox' is operated, have also been used with some success, but are also too slow in operating to work a standard shovel to its capacity.

A machine designed and manufactured in Germany has been used in that country and in Siberia with considerable success. It has a ladder and bucket-line similar to an ordinary gold-dredge; the machine is on a track on the surface in front of and at right angles to the direction of the cut, the ladder and bucket-line extending down into the cut and the buckets being dragged against the bank and digging it away as in the case of an ordinary dredge. The material is brought up over a tippie and dumped upon a belt-conveyor, and thence passed to the spoil bank. The material is dug dry, and the machine digs the ordinary river gravel fairly well. The buckets are not large, and the feed to the belt is sufficiently regular so that this form of conveyor can be successfully used. It is said to be an efficient and economical excavator and has been used as such successfully over a period of years. Putting conveyor-belts on these machines is a new departure, but it is reported to be giving satisfaction. Previously the machine delivered the material into cars for removal.

The types of excavators described in this article are the ones principally used in cutting wide deep trenches, and in stripping operations where the overburden is considerable and it is desirable to stack the spoil along the sides of the cut. There are other types of excavators doing good work in digging the smaller irrigating and drainage canals, and for cutting trenches and digging ditches, but their description is hardly within the scope of this article. As an excavator, the California ladder-bucket dredge is undoubtedly far superior to any of the above mentioned, and where the material can be so dug, its gold contents won on tables placed on the dredge, and the gravel disposed of immediately behind the boat, this is undoubtedly the cheapest method of handling the material. But the conditions are not always favorable for dredging. It may be desirable to remove and stack the overburden and subsequently mine and wash the pay-gravel, and in that instance one of the methods of excavating above mentioned may prove of value. Moreover, these methods, or some one of them, may be profitably applied to forms of excavating other than the handling of gravel, such as the stripping of coal and iron ores, digging canals, or other similar work.

The best type of excavator for any particular work depends largely on the amount of material to be handled, assuming that two or more types will efficiently dig and stack the spoil. The revolving long-boom, drag-line bucket machine is much cheaper to install than would be a steam-shovel of large size and very long boom, and although the actual operating cost of handling per cubic yard might be somewhat in excess of that with the steam-shovel, the lower amortization charges on the drag-line installation might more than compensate for this. Consideration of the value of each machine after completion of the contemplated work must be taken into account, and here locality, transporta-

CLASS 14, BUCYRUS, DRAG-LINE SCRAPER, WITH 60-FT. BOOM, AND  $1\frac{1}{2}$ -YD. BUCKET, MAKING A RAILROAD FILL.

tion facilities, and prospects of future work are important factors. The heaviest part of the drag-line machine and its total weight being very much less than that of a large-boom, heavy, revolving steam-shovel, it may be successfully taken to localities where it would be impracticable to transport the shovel. Where it is necessary to erect a second machine for stacking to be used in conjunction with a standard steam-shovel, the same consideration as to first cost and future value must be taken into account. Moreover, inasmuch as the standard shovel requires the laying of tracks, always an expensive item in steam-shovel operations, and other tracks have to be laid for any form of successful stacker yet devised, and as no machine other than the expensive incline tippie, previously mentioned in this article, seems able to keep a standard steam-shovel constantly working, it is a question as to whether the operating cost per yard with the drag-line machine would not prove less than the double-handling method where the drag-line machine is capable of digging the material. The shovel requires its full complement of operators and track-layers without being operated to anything like its full capacity. Where the drag-line machine can dig efficiently, by the use of a large bucket, one set of men can handle a substantial yardage at a comparatively low operating cost.

## Pioneer Company of Siberia, Ltd.

By C. W. PURINGTON

The gold-dredging possibilities of the lower Amur region in East Siberia are being thoroughly investigated this season by a corps of engineers under the direction of Ross B. Hoffmann, of Oakland. The Pioneer company has acquired by location nearly 100,000 acres of dredging land within a radius of two hundred miles of the city of Nikolaievsk. The areas are situated on and adjacent to some twenty different creeks and rivers tributary to the Amur river, and to the Amgun river. The country rock of this district is slate and schist, extending with great uniformity of occurrence over enormous areas. Small quartz veins interlaminated with the schist have supplied the alluvial gold. The gold occurs finely divided and averages \$18 per ounce in value.

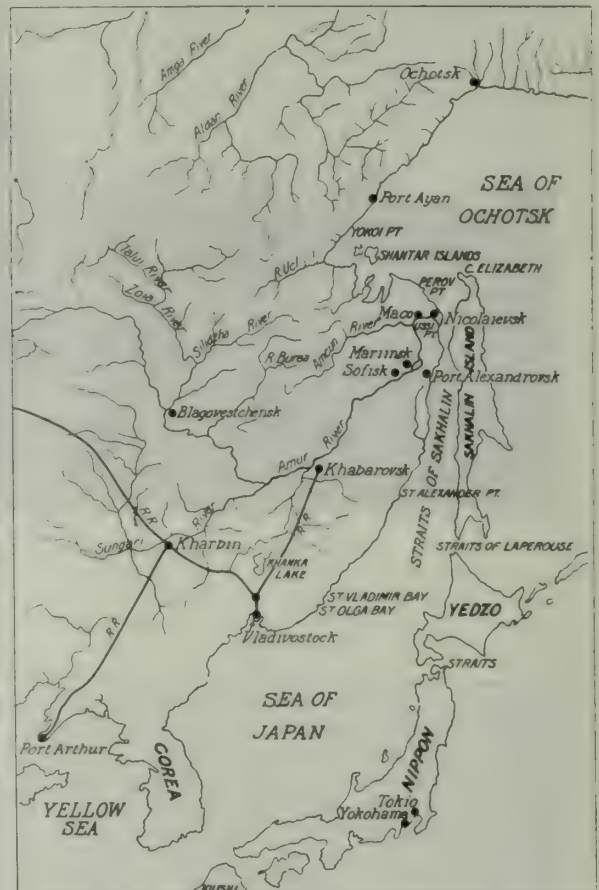

The region has been for many years the scene of a desultory mining activity, the rich gravels at the headwaters of the streams having been worked by hand methods. Since 1869, it may be estimated that a product of \$30,000,000 in placer gold has been obtained, by laborious and wasteful methods. The old properties are now for the most part exhausted and for sale, but even though they contain valuable gravel they are of little importance, as they occupy small and isolated creeks near the head of the river systems and are almost impossible of access for the transport of machinery. Besides this, the tailing has been stacked in such a way that to re-work it by dredging is difficult and expensive.

The Pioneer company has adopted the policy for the most part of locating, through specially granted permits, the gravel flats below these old properties where suitable dredging conditions are known to exist, and which are accessible directly by water transportation. Government patents to these claims are being obtained as fast as desirable, and it is expected that before the end of the year several thousand acres will have been patented. In the meantime prospecting rights have been granted and the drilling of the ground is proceeding. Several of the properties held by the company, as, for example, the Somnine, the Semi-Amgun, the Nummul, the Geri, and the Pilda, appear to contain an amount of gravel in continuous areas on the scale of the larger California properties, and there are several smaller areas where rich deposits have been indicated by the operations of the so-called *hishniki* or illegal wandering gold miners of the country.

The region is one of comparatively low latitude, being about 53° north, and permanent frost is not found at all,

or only in very small quantity. The operations of the dredges of the Orsk Goldfields, and the dredge belonging to the Amgun company have shown that favorable conditions for dredging exist, and it is estimated that gravels carrying 20c. per cubic yard recoverable gold, if found in large quantity, can be made to pay. It is hoped that during the season at least one of the large properties will be found sufficiently promising to warrant sampling in detail. Permanent frost is not found in any quantity in any of the areas under location. A little frost is found in the upper Amgun properties, but not elsewhere, so far as known.

The region has the advantage that it is incapable of wheat growing or supporting an agricultural population,

EASTERN SIBERIA AND JAPAN.

consequently it is practically empty except for the mining and fishing population. No agricultural rights are likely to hinder the dredging industry. The labor is mostly Chinese, and entirely satisfactory for all drilling and pit-sinking work, and also for dredge-construction purposes. It has also been found that dredge operators can be trained from among the Russian mechanics, especially those from the Baltic provinces. There is an abundant supply of timber in the region for fuel purposes, prices ranging from \$1 to \$1.50 per cord for spruce wood or birch, as the case may be, cut and delivered at the boilers. There is little timber suitable for construction work, and dredge hulls must for the most part be of steel. Housing lumber can easily be obtained locally. For a large dredging enterprise implying a central power plant to operate several dredges, it would probably be advisable to import crude oil in tank steamers from the Black Sea.

It has been found by experience that the season for gold-dredging lasts from seven to eight months. The region enjoys a superb climate and abounds in fish and game. A bi-monthly service of steamers is maintained during the summer between Hamburg and Nikolaievsk, by way of Suez. For passengers Nikolaievsk can be reached by way of Trans-Siberia from London in seventeen days.

## Australian Mining Laws

By A. MONTGOMERY

\*For a good many years past most of the governments of the Australian states have adopted as a principle that when Crown lands are sold, granted, or leased, the demise does not include mineral rights of any sort as regards the precious metals and the more important metallic minerals. A person buying land for purposes of residence, cultivation, or any other ordinary occupation not depending on minerals in the land, is presumed to have obtained it for the ostensible purpose for which it was taken up, and not for unknown mineral values which it may ultimately prove to contain. The state and the purchaser then both know what part of the public estate is being treated for, and neither party has any call to be aggrieved if subsequent discoveries show that the land had mineral values in it which were not contemplated in the original transaction. The principle is not, however, carried out by any means completely, or to its logical conclusion of reserving to the state all values which may accrue to the land in the course of time from considerations not contemplated at the time of the original transaction, namely, 'unearned increments' due to position. All minerals are not strictly reserved, the land-owner being, as a rule, entitled to all benefit of such products as clays, slate, building stone, limestone, and similar minerals.

The older Australian titles included all minerals in the fee simple of the land except the precious metals, and in a few cases even these were specially included also. These rights have rarely, if ever, been interfered with. In the case of lands over which the mineral rights have been reserved at time of sale, it is in practice so difficult to effect entry upon private lands to search for and work minerals, except with the consent of the owner secured by definite agreement with him, that it is rather uncommon for any attempt to be made to force them open for mineral selection, and the greatest practical difference between this case and that in which the land-owner owns the minerals, is that the latter is not in any fear of compulsory resumption of his land by the government, at a valuation which takes no account of the mineral values, for the purpose of having it thrown open for mining operations, and consequently is free from the pressure which may be exercised upon the former class of owners to induce them more readily to admit mining on their lands on what they may consider unduly easy terms. The land-owner remains in a pretty strong position, however, even if the minerals do not belong to him, as it is usually easier to make terms with him for entry upon his land than to get the machinery of government to work to have the ground resumed for mining purposes with consequential compensation of the land-owner.

The general trend of Australasian legislation on this matter appears to be toward more rather than less restriction of the land-owner's rights, confining them to use of the surface for the purposes for which it was declared to be occupied, and toward greater facilities for mining adventurers to enter upon such lands in search of minerals and to work them without hindrance from the land-owner. This seems quite a logical outcome of the root idea that the lands of the country belong to the state, and that the surface is open to be sold to one owner for agriculture or any other declared purpose, while the mineral rights, with necessary way-leaves to work them, may be sold or leased to another person without more reference to the first than to fairly compensate him for the interference with his possession of the surface entailed by allowing mining on his land.

\*Extract from reply to the circular letter of the committee of the M. & M. Soc. Amer. on revision of the American Land Law.

Much the same idea underlies the strong preference shown in this part of the world for leasehold tenure of mining lands as against freehold. The mineral rights are granted by the state on easy terms on the condition that they are worked, and that if not worked they revert to the state, a condition much more readily enforceable with leases than with freeholds. The mining investor's point of view is naturally a different one, and among such there is a strong desire for the fee simple, in order to be able to retain the mineral rights without working the mines, if their interests seem to them to make inaction the best course. Where a mine has been worked and has come to the end of its resources for the time being, there is a good deal to be said for the freehold tenure, as it gives better opportunities to the owners to await the chances of sale of their property, or of recuperating their finances. From the state point of view, however—which is very similar to that taken by a private owner of mineral lands when he lets portions of his ground for mining purposes—the most essential consideration is to have the ground worked, and if not worked by the first holder, to be thrown open as soon as possible for anyone else desirous of coming in to work it. The terms given by the Australasian states to their mining lessees compares very favorably indeed with those commonly granted in the United Kingdom by land-owners to the mining companies and others who take mines on lease, as regards continuity and scale of working. The administration of the law is also usually much less harsh than is permitted by the letter of the statutes, the governments taking powers to act in these which they need not necessarily enforce to the utmost unless the circumstances seem to require their full exercise. In this, also, they follow the example of most private land-owners, who require discretion to be left with them as to how much more or less strictly they may enforce the conditions of their mining leases, and the less personal and more public-spirited views taken by members of a government as compared with private land-holders may be relied upon to effect greater consideration for the mineral lessees.

Preference for a freehold or leasehold tenure of mining lands depends greatly on the nature of the interests of the parties concerned, and in considering the principle most expedient for a state to adopt, regard must be had to the predominance of interests. If the matter of greatest moment is to attract the capital of investors to the development of the state's mineral resources, it may be politic to meet their views upon security of tenure and allow them to acquire the freeholds which they so much desire, with complete control of their future development entirely at their own will. This is the bargain which appears to appeal most strongly to capitalists, and to secure their support a state may think it best to offer them a proposition to their liking. If, however, the state prefers to keep the control of its mineral lands in its own hands, to prevent their being locked up for years for speculative purposes, and to offer facilities for the location and working of mines by parties of its citizens who may have little or no capital but their labor, the leasehold system seems entirely preferable. It is to be remembered that in framing legislation the state has decision of its policy altogether in its own control, and has a right to settle it in what it considers to be its own best interests, and at one stage of its development it may well find it most expedient to offer its mines on freehold terms, and at another to change more or less entirely to a leasehold system. Where the immediate support of capital is not of prime importance, the leasehold system appears to me to be usually more in the best interests of the state than the freehold one, and in making its laws it is surely for the

state to consider its own interests first, to the subordination of all others. The mining laws express the terms on which the state offers its mineral lands for exploitation, and should be drawn up to conserve the interests of the state first and foremost, studying those of outsiders only from the point of view of benefits to accrue to the state. The mining investor who clamors for all sorts of concessions from the state in return for putting his money into its mines rarely appears to consider that the state has any rights, and looks at the proposition entirely from his own point of view, and is apt to agitate for legislation on lines designed entirely to further the investor's interests without any regard to those of the state. This is natural enough, but what would one think of a statesman who in advocating outside interests should forget their duty to their own state?

In discussing the lines on which mining legislation should proceed, therefore, the members of the Mining and Metallurgical Society should remember to hold the balance clearly between the somewhat opposing interests of the buyer (the mining investor) and the seller (the state) of the mineral lands, and take a wide view of the question, looking at what is best for the development of the mineral industry as a whole, with due consideration of the points of view of both parties. There must be more or less of a compromise, to encourage the investor to the utmost to open up mines by giving him good security of tenure and all reasonable latitude in development and working, while at the same time conserving the state's interests by preventing mineral lands from being locked up and monopolized without being worked. It may be prejudice owing to being accustomed to the leasehold system, but it appears to me that leasehold tenure offers a better basis of negotiation in this respect than can be obtained from any freehold system. Australian experience of mining freeholds has been anything but encouraging.

The above remarks cover a good deal of your questions No. 1, 2, and 3. As regards initiation of mining rights, the Australian practice is based on priority of right to be allotted, mineral lands being given to the discoverer of valuable minerals, and the 'miner's right' system gives him a large measure of security in at once taking possession of the ground. Priority of pegging out ground and applying for lease thereof is also fully recognized in issuing leasehold titles, and a discoverer usually protects himself by applying for a lease as soon as possible after making a valuable discovery. The system of prospecting licenses in vogue in Western Australia allows time to a prospector to test a piece of ground before taking it up on lease, and has proved very useful. It is not customary here to insist that minerals shall have been actually found on ground applied for before a lease is issued, and it very commonly happens that 'position blocks' are taken up all around a new discovery in the hope that subsequent prospecting may find something on them. The obligation to work these blocks under pain of forfeiture leads to their being pretty closely searched for minerals, and if an owner is lax in this respect, he knows that others may apply for the ground over his head, on the ground of his insufficient working, and get it away from him. There has often been a question raised if it would not be better to require some actual discovery to be made before a lease is issued, but the present system works very well, and enables people to secure a piece of land for their own uninterrupted prospecting, which is more generally satisfactory than if no one had a title to the land until an actual discovery was made.

The question of terms of renewal of mining leases is one on which there is much difference of opinion in Australasia, but as a matter of practice there have been few instances of the terms for renewal of leases for a second or third term being made very seriously different from those of the first term. The good sense of governments comes in here, and their impersonal interest in the matter, to ensure that renewals are dealt with on broad and general principles and not on any rack-renting policy which

might commend itself to a private owner of land in a like position. Most of the state governments reserve the right to impose increased rental and sometimes royalty in the event of granting a renewed term of lease, but I am not aware of any instance of its being exercised to any extortionate extent.

Most of the Australasian states grant much larger leases of land for coal and other minerals which are of low value per ton, and are worked out rapidly over large areas, than for metallic minerals, and generally mineral leases for tin, lead, bismuth, and other base metals are of larger areas than are allowed for gold. It is difficult to see any very sound reason for differentiating in the areas allowed on, say, gold and tin lodes, as the nature of the workings is quite similar and also the rate of exploitation. Ton for ton, both sorts of ore are of much the same net value, and it is immaterial to the owner who gets a profit of a dollar a ton whether it comes from gold or tin. The difference in areas leased appears to be merely a concession to popular ideas that gold mines are naturally more profitable than those of base metals, which of course is entirely a misconception. The principle which should govern the extent of ground to be granted seems rather to be rate of exploitation than value of mineral, the area to be granted being such as—taking into account the mode of occurrence of the ore—will allow the leaseholder ample time to work his mine long enough to make it well worth his while to undertake the proposition and ensure redemption of his capital expenditure before the mine is worked out.

The extralateral right principle obtaining in portions of the United States is a standing marvel to the rest of the world, and that it could be seriously proposed to perpetuate it outside of cases in which it has unfortunately already been granted, seems incredible to most outside engineers with whom I have come in contact. If all ore deposits could be relied upon to behave themselves in accordance with elementary diagrams in the text-books representing a few of the simpler occurrences of fissure veins, there might be some hope of maintaining the extralateral right system on consistent and logical grounds, but since their forms are in fact protean and never predictable with any real certainty, and since even the best authorities differ, often radically, in their views as to the nature and origin of the ore occurrences, there seems no hope of attaining such precise legal definitions as will serve to justly decide all cases of extralateral right. The claim of the discoverer to follow out his discovery in all its ramifications has a certain amount of apparent justice, but is practically impossible to be granted in very many cases without infringing upon the equal rights of others. If the first man to obtain petroleum by boring, for example, were to have the right to all petroleum that would come to his wells, thus exercising the right of the discoverer to its utmost, he should be protected from the boring operations of neighbors, whose bores may and probably will tap oil that otherwise would flow to the discoverer's well. What a lovely problem for courts to decide, on the evidence of 'expert' witnesses, whether bore A would have got the oil obtained from a neighbor's bore B if the latter had not been made! Again, in coal-seams or any bedded deposits, should a discoverer have an extralateral right to follow his discovery beyond the limits of his location? If so, he should monopolize the whole seam, but if he is not given this right, why should it be given in the case of a lode? Some limit has to be placed on the rights of the discoverer, and it is surely best to follow the same principles as obtain in all other occupancy of land and confine his operations within the boundaries of the land he has located.

BISMUTH-BEARING ORE, so far as known to the U. S. Geological Survey, was produced in this country during 1911 in La Plata county, Colorado. Ore mined here contains 6 to 8% bismuth. This ore, however, was sold for its gold and silver content. Another lot of still richer ore was mined from a claim about 35 miles southwest of Tularosa, New Mexico.

# Genesis of the Lead-Silver Ores of Wardner District, Idaho

By F. L. RANSOME

Under the above title, Oscar H. Hershey has recently contributed to the *Mining and Scientific Press*<sup>1</sup> a valuable and interesting paper in which he presents briefly some results of a detailed study that extended over a period of nearly two years and occupied his time fully for over 18 months. Thorough discussion of the points wherein Mr. Hershey differs from the conclusions previously reached by Ransome and Calkins<sup>2</sup> would be possible only after some re-examination of the field by these geologists with particular reference to the issues raised. This is not immediately practicable, but those interested in the district and in the articles mentioned may reasonably expect some present comment from one of the geologists who wrote what Mr. Hershey kindly refers to as "the standard work of reference in the district." In attempting to meet this expectation, I have no intention of adverting to every point brought up by Mr. Hershey, nor of continuing the discussion beyond this brief communication.

The Wardner district, it should be noted, in introduction, comprises but a small portion, perhaps not more than one-tenth, of the area to which F. C. Calkins was able to devote about six months, and I about three months, in field study a few years ago as a basis for our report on the Coeur d'Alene district.

This report supplied Mr. Hershey with a broad foundation of ascertained geologic facts upon which to build, so that with the advantages of extensive mining development since the Federal geologists left the field, and of the exceptional facilities afforded him by the Bunker Hill & Sullivan Mining & Concentrating Co., it would be strange if so capable a geologist found nothing to contribute to our knowledge of the ore deposits. When, however, Mr. Hershey states that "previous to this [that is, his own work] no detailed geological study of the mines had been made, although the areal geology of most of the district had been mapped in 1903 or 1904 by F. C. Calkins \* \* \* and the mines visited<sup>3</sup> by F. L. Ransome", and that "Mr. Calkins found that the structure in the Wardner district is too complex and obscure to enable him to do any but very generalized mapping in the time that he could give to the work", those who first gave a comprehensive account of the geology and ore deposits of the district may perhaps be pardoned for taking exception to the probably unintentional disparagement of their work conveyed by his form of expression. The opportunities enjoyed by Mr. Hershey for prolonged study of a single group of orebodies were exceptional, and his work was so different from anything that is practicable in the general geologic study of a region where perhaps a fortnight is all that can be spared for examining a single large mine and grasping its essential characteristics, as scarcely to afford a fair basis from which to impugn more rapid work as necessarily lacking in detail or essential accuracy. If, in addition to unraveling the general stratigraphy and structure of the district, the Government geologists had studied the whole field with the same leisurely attention that Mr. Hershey has focused upon a small part of it, their examinations of the mines might not have been dismissed by him as mere "visits"; but their field work would have lasted from ten to twenty years, and the results, such as they are, would not have been available as a starting point for his own investigation. The atmosphere having been cleared of cloud by this preliminary protest, attention may now be given to more important matters.

In his discussion of the geology of the Wardner district, Mr. Hershey has locally subdivided the Revett quartzite as originally defined by Calkins into three members, and the Burke formation into two members. He has also added to the bottom of the stratigraphic column the Cataldo formation, a quartzite exposed west of the Coeur d'Alene district and interpreted by him (whether correctly or not, I am unable at present to say) as underlying the Prichard, whose base is not exposed at the surface in the area studied by Ransome and Calkins. In addition to a few great faults mapped and described by those authors in the Wardner area, Mr. Hershey has platted and named over 90 faults which he divides into nine systems "each representing a distinct period and stress." The small outline map accompanying his paper is not adequate for a full discussion of Mr. Hershey's treatment of the faulting. It is possible that all of the 97 faults exist as they are platted and that each is definitely referable to the appropriate one of the nine systems. Knowing something of the soil-mantled and brush-covered slopes in that region, however, I can only wonder how Mr. Hershey did it, and hope that some time we may have an opportunity to review the ground together. Of course, many of the faults were discovered and mapped by him in the mines, but this scarcely detracts from the remarkable character of the network of fissures shown on his map.

Mr. Hershey distinguishes no less than 12 distinct and successive periods of "mineralization." The oldest type of mineralization is that represented by disseminated siderite. Mr. Hershey's "impression" is that this dissemination of ferrous carbonate antedated the monzonite intrusions and the mineral may have been deposited with the sediments, possibly in the Prichard formation. Next in order of age are deposits of contact metamorphic character, not well represented in the Wardner district. Then follow ten types of mineralization of which the first eight are each connected with one of the first eight systems of faults, while the last two are connected with the ninth system. Mr. Hershey's conclusions are briefly summarized in his own words as follows:

"I favor the theory that the lead, silver, and zinc minerals of the Wardner district were originally disseminated through certain bands of the Belt sediments; were first concentrated into the visible disseminated zinc and lead deposits through the action of the heat and probably water emanating from a monzonite magma; and were then concentrated into commercial orebodies by hot waters that were forced to ascend by the compressive stresses that produced the thrust faults, these thrusts opening the fissures in connection with which the ores have been deposited. The ores of each successive stage have probably been derived in part from those of earlier ore-forming stages, in part from the visible disseminated deposits, and in part from the original minute disseminations in the sediments."

My own view of the genesis of the Coeur d'Alene ores, as presented in Professional Paper No. 62,<sup>4</sup> is, very briefly, that the fissuring of the district was due to stresses set up during the intrusion and solidification of the great quartz monzonite batholith of central Idaho, of which the exposed monzonitic masses in the Coeur d'Alene district are probably offshoots, and that the ore constituents, inclusive of the siderite but probably exclusive of some of the quartz, were given off as emanations from the deep-seated portions of the slowly crystallizing batholith. Among the facts adduced in support of these conclusions was the mineralogical connection, through deposits of intermediate character, of the orebodies of the Wardner type with others in the same region that are genetically connected with contact metamorphic action.

It will be seen that Mr. Hershey agrees that the ore-

<sup>1</sup>June 1, 1912, pp. 750-753; June 8, 1912, pp. 786-790; and July 15, 1912, pp. 825-827.

<sup>2</sup>"Geology and Ore Deposits of the Coeur d'Alene District, Idaho." U. S. Geol. Surv., Prof. Paper No. 62, 1908.

<sup>3</sup>Italics by F. L. Ransome.

bearing solutions were hot, were under heavy pressure, and came from below. He agrees further that some of the older mineralizations—namely, the lead-zinc disseminations—were formed by water expelled from the monzonite, although he thinks the lead and zinc may have been leached from the sediments. But having, as he believes, established twelve periods of mineralization, ten of them connected with nine systems of faults of different ages, he maintains that the process of ore deposition must have extended over too long a time to be all referable to a cooling batholith.

His conception is that at each period of reverse faulting the stresses that produced the faulting heated the water that he supposes to be present in the rocks at great depth and forced it upward, and that this water, after dissolving the disseminated ore constituents from the rocks traversed, or after attacking ore deposits that had been previously formed, deposited its burden in a higher part of the fissure as a body of commercial ore. In connection with this view he explains a supposed association of ore deposits with reverse faults by the suggestion that "normal faulting makes stronger gouges than reverse faulting, and gouges were distinctly inimical to the deposition of mineral." The first part of the suggestion is questionable; the second part paraphrases a conclusion expressed in Professional Paper No. 62.

Mr. Hershey's hypothesis is both novel and ingenious, but while it would be unfair to expect him to marshal all of his significant facts in a short paper, nevertheless his presentation, in view of the work previously done in the district, appears deficient in evidence. For example, his "impression" is that the disseminated siderite antedated the monzonite intrusion, but he gives no real evidence for this view, and on the same page states that the siderite "in its present form" is younger than the metamorphism. An impression unsupported by definite evidence is certainly not a very formidable missile to hurl at a conclusion previously entrenched in the field. He believes that the materials for the orebodies as they were successively formed were leached from older deposits, but I have been unable to find in his paper any facts, mineralogical or otherwise, in support of this belief, or any clear evidence that the disseminated ores are not all younger than the monzonite. Above all, a geologist who has studied the region without seeing these things, may be pardoned some curiosity to know how Mr. Hershey establishes so definitely that the nine systems of faults are of different ages and that each system has associated with it a distinct type of mineralization. One such geologist, at least, awaits more evidence before accepting as a fact so remarkable a sequence of faulting and ore deposition—a sequence so elaborate that, if true, any worker of experience must know that it could be recognized and established only under ideal conditions of observation. Mr. Hershey, I think, fails to appreciate in their full significance the gradations in character worked out in Professional Paper 62 between the garnetiferous deposits near the monzonite and deposits of the Wardner type, or the widespread development of tourmaline in the Coeur d'Alene sedimentary rocks. Moreover, even if it be granted that there has been successive faulting followed in each case by ore deposition, the advancement of this alleged fact as an argument against a genetic relationship between the solidifying of a batholith and the formation of the orebodies carries with it the implication of a quicker cooling and solidification on the part of a deeply buried batholith, particularly the deeper portions of such batholith, than most geologists perhaps will admit. At all events, too little is known of the depth and rate of cooling of such a mass to lend much force to the contention that manifold faulting and ore deposition could not have taken place concurrently with cooling, which possibly is still in progress. This view appears to encounter fewer difficulties than does Mr. Hershey's suggestion of deep-seated supplies of water, squeezed out by fault-movements and acting as an energetic solvent and carrier of ore constituents.

In conclusion, while admitting that the questions relating to ore genesis are too obscure for geologists to reach unanimity upon them within our generation, and while welcoming Mr. Hershey's suggestions as worthy of consideration and investigation, I do not feel that he has brought out such evidence in their favor as to justify their general acceptance, or to necessitate any essential change in the hypothesis of ore genesis given in Professional Paper No. 62.

## Gold and Diamonds in British Guiana\*

*Historical.*—It is not definitely known when gold was first discovered in British Guiana, but the first expedition in search of it was made in 1720 up the Berbice river. In 1863 the first well organized attempt was carried out by a company up the Cuyuni river, and gold-bearing quartz was then discovered at Wariri, on the right bank of that river, about 25 miles from the mouth. The project, was, however, abandoned, owing to the district being in dispute between British Guiana and Venezuela. Eventually, in the eighties, attention was again directed to the auriferous possibilities of the colony, and after several expeditions up the Essequibo, Mazaruni, and Cuyuni, the gold industry became established in 1886, and the first set of mining regulations was passed in that year. From that date the industry developed rapidly, and the gold production rose steadily in each year, until it reached the highest record in 1893-94 with 138,528 oz. In recent years the production of gold has averaged about 82,000 oz., but the production is still falling.

*Distribution of Gold.*—The gold-bearing areas are widely distributed throughout the colony. Gold has been found in all the rivers, with the exception of the Corentyne and the Berbice, but traces have been found in the latter. The districts of the colony where mining has been carried on are those adjoining the Essequibo river and its tributaries, the Potaro and the Konawaruk; the Mazuruni and its tributary the Puruni; the Cuyuni, the Barima, Barama, and Waini rivers in the northwest; and the upper Demerara; and a new field has been discovered on the Wenamu, a branch of the Cuyuni, and part of the boundary line between the Colony and Venezuela. The gold from the Wenamu is very coarse, the overburden lying on the gravel being very shallow, and the 'pay-dirt' deep and rich. The government geologist, who has made a reconnaissance of the gold-bearing areas of the colony, states that "the gold is found widely diffused in the districts occupied by the Archean rocks, but usually only in profitable quantities near intrusions of basic rocks. The basic rocks belong to at least two periods: (1) those of the gneiss formation, probably originally gabbro and diabase, but now quartz-diorite, apodiorite, amphibolite, or hornblende schist; and (2) the unaltered diabase which is of later origin than the sandstone formation." All the fields have proved of good value, and rich finds have been made in each; perhaps the most valuable field for its size being at Omai on the left bank of the Essequibo river, from which place over 95,000 oz. has been obtained, from an area of about 60 acres.

*Production of Gold.*—The following is the amount of gold recorded at the Department of Lands and Mines since 1884:

	Oz.
From 1884 to 1905 .....	1,756,630
1905-06 .....	94,363
1906-07 .....	85,505
1907-08 .....	67,209
1908-09 .....	73,655
1909-10 .....	64,830
Total .....	2,142,192

\*Prepared by the Committee on Permanent Exhibitions.

The total value of the above amount is £7,810,075. Fine gold occurs in places, but as a rule the gold saved in this colony is coarse. The largest nuggets are one of 333 oz., from the Five Stars district, on the upper Barima river, and one of 11½ oz., from the Tiger creek, Potaro.

**Methods of Working.**—The major portion of the gold obtained has been from alluvial washing. Auriferous quartz has been discovered and worked successfully at the Peter's mine, in the Puruni river, at the Aremu mine, in the Cuyuni and at the Barima mine, near Arakaka in the Barima. The Peter's mine started crushing operations in September 1905, and up to March 31, 1910, obtained 39,017 oz. of gold. Dredging is also being successfully carried on in the Konawaruk river. Four dredges are now at work in this river, and from the commencement of operations in December 1906 the company has obtained 11,496 oz. of gold. Another company is also successfully working a dredge on Minnehaha creek, a tributary of the upper Konawaruk. Hydraulic mining was carried on for three years at Omai, during which time 27,123 oz. of gold was obtained. Similar work is now being carried on at the Tassawini mine, in Barima river.

**Diamonds.**—Diamond mining was first started on the upper Mazaruni at Patareng creek, and is still being carried on in that district. Diamonds have also been discovered in the country around the Kuribrong and Cuyuni rivers. The stones are found over a fairly large area in the Mazaruni, and are obtained by washing the gravel in which they lie in a similar manner as is carried on for gold, which is often found with diamonds. The following is the production of diamonds for the last 5 years in carats: 1905-06, 4097 5/16; 1906-07, 4661 3/8; 1907-08, 2121 11/16; 1908-1909, 5617 5/8; 1909-10, 7180 13/16. The stones are of good quality, and run on an average from 10 to 15 to the carat, though some large stones have been found, two quite recently, weighing 12½ and 12¼ carats, respectively.

**Mining Regulations.**—The mining regulations of British Guiana are simple and generous. A prospecting license available for one year from issue can be obtained for \$5 (20s. 10d.), and this permits the holder to roam the colony, and to locate any number of claims, of a size not exceeding 1500 by 800 ft. (27½ acres), for gold, and of an area not exceeding 500 acres for diamonds. On each gold claim a rental of \$5 per annum must be paid, and on each diamond claim 20c. (10d.) per acre. These rentals are due on the first of April of each year. All claims, the rentals for which are not paid by the Tuesday following the third Saturday in June, are sold at auction on that day, and if not sold are revoked and the land again becomes open to location. 'Exclusive Permissions', or really 'Exploration Permissions', can be obtained for 3 years in the payment of \$10 (£2 1s. 8d.) filing fee, and an annual rental of 7½c. per acre, giving the holder the sole right to prospect over large areas of country. These are of great value to the prospector in a new and untried district. As soon as he discovers that the district in which he is prospecting carries gold in profitable quantities, he can take out one of these permissions and so give himself ample time to carefully prospect and locate all the claims he requires, before being crowded out by the rush that always follows a successful find. After locating the claims he desires, the holder of the permission can surrender it, retaining of course such portions as he has located, and for which he then obtains a claim license. Mining concessions or leases for 99 years or under, can be obtained for any area on payment of \$10 with application, and an annual rental of 20c. (10d.) per acre. These concessions are suitable in cases where the work to be carried on is of a permanent nature and necessitates the expenditure of large capital, as they are not open to automatic revocation for non-payment of rental in the way an ordinary claim license is, every June. Dredging concessions for the rivers and creeks can also be obtained on similar terms; in this case, however, the rental is only 10c. (5d.) per acre per annum.

**Royalties.**—The royalty on gold is 70c. (2s. 11d.) per

ounce and 4c. (2d.) per ounce on silver, but all gold and silver obtained by milling pays a tax on profits of 5% in lieu of royalty. Diamonds found in prospecting pay a royalty of 10% of their value, but when obtained from a claim a fee of \$25 (£5 4s. 2d.) per quarter acre is charged for all land worked, and no royalty is payable in that case. All gold, silver, and diamonds must be reported on arrival in Georgetown at the Department of Lands and Mines.

**Administration.**—The colony is divided into mining districts, each under the control of an officer of the Department of Lands and Mines styled Warden or Sub-Warden, who has power to settle all disputes as to claims, and who is continually traversing the district, and whose help and assistance in carrying out the regulations is therefore easily obtained.

**Transport.**—The colony being so intersected by rivers, the general means of transport is by water, and the facilities are good. There is steamer communication from Georgetown to all the centres of the districts, from where boats and crews can easily be obtained to cover the remainder of the journey at a reasonable cost.

**Labor.**—The men generally employed in the gold and diamond industries are negroes, natives of the colony, and from the West India Islands, and a few from Dutch and French Guiana. They are strong and capable of great endurance, and are well fitted for the work. All laborers, with the exception of aboriginal Indians, must be registered by the Institute of Mines and Forests, whose head office is in Georgetown, with branches in all districts. They are generally engaged to serve for a period of three or four months, and the daily wage paid ranges from 36c. (1s. 6d.) to 72c. (3s.) for ordinary unskilled men. The mining regulations require that all laborers must be supplied with rations according to a scale fixed by the Government. The shops which exist in all districts will arrange to supply the men these rations at from 20c. (10d.) to 30c. (1s. 3d.) per man per day, according to the district. Qualified dispensers are required to be kept on all claims where 50 men or over are employed, and certain medicines for their use must also be kept on the claim. Failure to pay laborers their wages within 14 days after they are due renders an employer liable to a fine of \$50 (£10 8s. 4d.) or imprisonment, and any laborer who fails to complete his contract is liable to a fine of \$48 (£10) or imprisonment.

BARYTES, in the form of crude ore, was produced in the United States in 1911 to the amount of 38,445 short tons, valued at \$122,792, according to the U. S. Geological Survey. Compared with the production of the preceding year, this was a decrease of 4530 tons in quantity, but an increase of \$1046 in value. The total quantity of refined barytes reported as sold by mills in 1911 was 39,611 short tons, valued at \$503,867. The greater part of the barytes produced in the United States is used as a pigment in the manufacture of mixed paints. It is also in the manufacture of lithopone, a white pigment. Other uses for the mineral are in the manufacture of rubber, wall paper, asbestos cement, and poker chips, and in tanning leather. A use of barytes reported from Italy is in the manufacture of gorgonzola cheese. The cheese receives a covering in the form of a thick heavy crust of the finely-ground material which has the property of affording just sufficient protection from aeration.

SULPHUR deposits in Wyoming are found in the upper portion of Sunlight basin, about 32 miles in a direct line northwest of Cody and 14 miles east of the eastern boundary of the Yellowstone National Park, according to a report (Bull. 530-O) issued by the U. S. Geological Survey. The deposits occur in seven isolated groups, six of which lie in a belt about three and one-half miles long. No sulphur has been produced from these deposits, and it is extremely improbable that they will be sources of production until the transportation facilities of the region are greatly improved.

# Geology of the Miami Copper Mine

By M. H. LOVEMAN

The mine of the Miami Copper Co., situated about six miles west of Globe, Arizona, lies within the area treated by F. L. Ransome in the Globe Folio of the U. S. Geological Survey. At the time that report was written, however, the extent and commercial value of the low-grade copper deposits around Miami were unknown, and the geology of that special section was touched upon only as it applied to several mines working higher-grade oxidized ores.

The ground owned by the Miami Copper Co. includes quite a variety of rock types, first in importance being the Pinal schist of the pre-Cambrian age, the principal, and in fact with one exception, the only rock carrying sulphide ores of a commercial grade. The schist is largely sedimentary in origin changed to its present form by extensive regional metamorphism accompanied by the introduction of a large amount of silica. In many places the severe crushing and recementing by silica gives it the appearance of a quartz breccia. In its normal form it is a muscovite schist, the muscovite being largely sericite. Intricately intermingled with the more common muscovite schist are considerable amounts of a biotite schist, probably, in part at least, formed from basic intrusions. The ore-bearing schist has been generally silicified to an extreme degree. On the surface it is of a pronounced red color, due to the oxidizing of the iron formerly present as pyrite. This gossan covering the Miami ore zone can be picked out from mountain summits many miles distant.

Next in importance is the Pinal schist in the Schultz granite, and its closely related offspring, a granite porphyry. The Schultz granite is intruded into the Pinal schist, and fragments of the latter included within the granite are common. That the granite is younger than the schist and older than the dacite of the region is the most that can be definitely said concerning its age. It is white in color, and its essential mineral is orthoclase, with some plagioclase, quartz, and biotite. Bordering the granite and radiating off from it are numerous dikes of granite porphyry. One such dike cuts east and west through the orebody and carries ore of the same grade and character as the enclosing schist. This is the single exception mentioned above to the exclusive occurrence of the ore in schist. This ore-bearing dike is from 25 to 60 ft. wide, dips south at about 60°, and runs entirely through the orebody. It is present at the greatest depth in the mine that has been so far developed. In the underground workings the true granite and schist are in no place in actual contact, but are always separated by from 30 to 75 ft. of what is either a granite porphyry or an altered granite. The fact that this zone is separated from the granite proper by a distinct fault plane, and that the change from one type to the other is generally sharp, would seem to indicate that it is a porphyry and not simply an altered phase of the granite. It is, however, undoubtedly derived from the same magma. This marginal zone sometimes carries copper to the amount of over 2%, but almost invariably in a highly oxidized form, and therefore not to be classed as ore. The granite proper in the vicinity of the orebody carries copper to the extent of about 0.7%, largely as euphriferous pyrite and chalcopyrite.

Dacite is present along the western and northwestern edges of the property, but is not found in the underground workings and appears to have no relation to the ore. Occurrences in other places have proved it to be younger than the ore. It is a biotite dacite occurring as flows, intruded sheets, and tuffs. The eastern portion of the property is overlain by the Gila conglomerate, a formation formed by the erosion of all the other rocks present in the district, but near the mine consisting largely of

boulders and sand derived from the schist and the granite. The conglomerate and the schist are separated by a fault, and, if amount of gouge, strong slickensiding, and excessive rounding of rock fragments are any criteria, the fault is one of considerable magnitude. As the dacite is younger than the ore, and the conglomerate in turn younger than the dacite, the faulting between the conglomerate and the schist evidently took place after the formation of the ore. The rather angular character of the fragments of schist in the conglomerate and the absence of sorting indicate very little movement by water. Numerous small dikes of diabase are encountered, generally copper stained.

In its general character the Miami resembles the other low-grade disseminated copper deposits of the West. In going downward from the surface the normal succession zones are passed through. First the leached zone or capping, varying in thickness from nothing to about 400 ft. From this zone the copper has all been leached, leaving a highly altered siliceous iron-stained schist. Next is the oxidized zone, containing carbonates and silicates of copper, some oxides and native copper, and considerable oxidized iron. This zone is variable in thickness, in some cases coming to the surface, in others being simply a thin layer above the sulphide zone, or, as is the case over a large portion of the orebody, being entirely absent. Bodies of oxidized ore have been found in the sulphide zone. This condition is probably in the majority of cases accounted for by faulting. The secondarily enriched sulphide zone lies below the oxidized zone and contains all the commercial ore of the mine. It varies from 200 to 400 ft. in thickness in the west and central portions, and the lower limits are as yet undetermined in the eastern part, where it seems likely that the thickness is somewhat greater. With greater depth it is probable that the amount of pyrite will increase and chalcocite decrease, marking the approach to the zone of original sulphides. This zone has never been reached in the Miami mine, as the one shaft which passes out of ore does so by reason of its entering granite rather than through its passing into original sulphides.

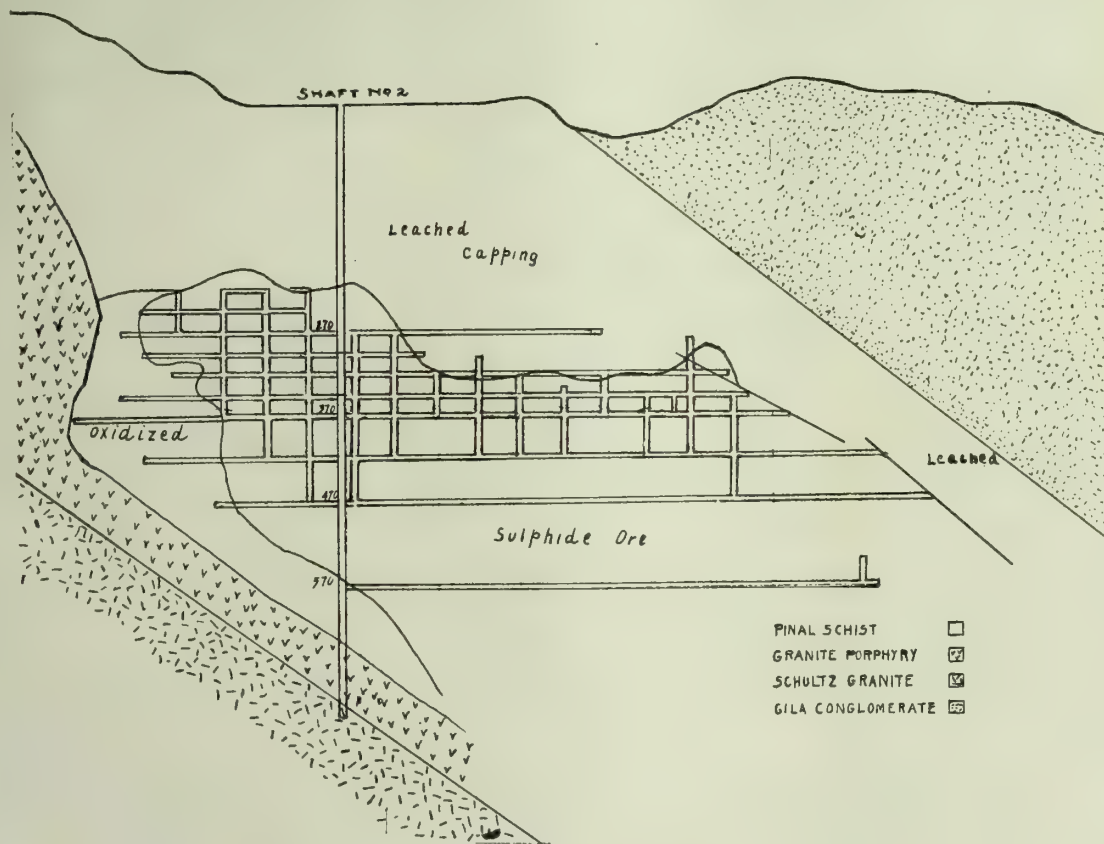

The shape of the orebody is extremely irregular. Its greatest east and west extent is roughly equal to its greatest north and south extent, but no two lines can be drawn at right angles representing these conditions, as the greatest western prolongation is in the northwest, the greatest eastern in about a central position, the greatest northern in the northwest, and the greatest southern slightly to the east of a central line. The upper limits of the orebody are also extremely irregular, rising and falling with apparently no definite system, although sometimes explainable by faulting. There is no discernible relation between the upper limits of the sulphide zone and the present contour of the surface. The lower limits, as before stated, have not been definitely determined. The irregular shape of the orebody is inevitable in a mine where in a number of directions the boundary is purely a commercial one, although in some places the ore either becomes low grade or is badly oxidized before reaching the actual limits. The Schultz granite marks the western edge; it strikes about 12° west of north (all directions are in mine coordinates) and dips about 38° east. This eastern dip causes the shaft in the orebody to pass through the schist into granite and gives the whole orebody a corresponding dip to the east. The southern boundary is V-shaped, formed by the granite contact just mentioned and by the contact between the schist and the conglomerate. This latter contact, which is marked by a large fault, strikes N. 43° E. and dips about 45° to the southeast. The fault plane is remarkably straight along both its strike and dip. In some places the ore persists to the actual contact, in others it is separated by a leached and crushed zone of as much as 80 ft. The eastern limits are also V-shaped, formed by the conglomerate contact and by a large fault striking N. 30° W. and dipping about 58° to the northeast. This fault above the 420-ft. level cuts the ore off clean; on the 420-ft. level and below, it appears to have had no

effect, and the ore limits are undetermined.

The mine is literally cut to pieces by faulting. The faults vary from those of apparently considerable magnitude to those of microscopic dimensions. Owing to an absence of recognizable horizons, the amount and even direction of the throw is generally undeterminable. In the minority of cases, however, the faults are undoubtedly of the normal or gravity type. A few instances of reverse faulting have been noticed, but these are of only a foot or two thrust. Faults can be observed with practically every possible strike and dip, but the majority can be grouped into two divisions, those striking northwest and dipping northeast, and those striking northeast and dipping southeast. The northeast-striking faults appear to be in most cases the older. Although the faults and dips are countless, only a comparatively few have any impor-

being too low in the last case for chalcopyrite. In its oxidized forms the copper is present as the carbonates, malachite and azurite, the latter in very small amounts; as the silicate, chrysocolla; as the oxides, cuprite, the latter often intimately mixed with iron oxides, and tenorite; although it has never been definitely recognized in this last form. The sulphate, chalcantite, has been found as fibrous incrustations on exposed surfaces where it has formed since the opening of the mine. Native copper is present along the margins of the sulphide body, occurring as films and in dendritic form. The iron minerals present are pyrite, hematite, and limonite. Chalcocite is the form in which the commercial ore is found, although small amounts of the oxidized forms are of necessity mined and are partly recovered in the mill. The chalcocite occurs as fine grains disseminated through the schist, as thin plates along minute

CROSS-SECTION OF THE MIAMI OREBODY.

tant effect upon the ore. With the exception of those described as limiting the orebody, only one other fault cuts off the ore for any considerable extent. This is a large one, cutting roughly through the centre of the mine, striking northwest and dipping northeast. The action of the fault through the ore is extremely irregular, in some places along its strike and dip it cuts the ore off sharply, while in others it has no effect whatever; the transition from one state to the other being often abrupt. These sudden changes are undoubtedly due to cross-faulting. In depth this fault, while still present, no longer affects the ore. A gradual dying out in depth is common to almost all the faults. The gouge and crushed matter becomes less pronounced and harder; this may be due to a decrease in the amount of water circulating along the fault-plane rather than to an actual diminishment in intensity of the fault itself. A good many of the faults do, however, affect the ore in a less marked degree. Along the larger ones there is generally a zone of a few feet on both sides of the fault-plane of oxidized ore, due to the freer passage of water along the crushed zone.

Copper, iron, and small amounts of gold, silver, molybdenum, and titanium are present in the orebody. Copper occurs in combination with sulphur as chalcopyrite, chalcocite, and as a cupriferous pyrite, the copper content

fractures, as a film on the surface of grains of pyrite and in more advanced stages in the replacement of the pyrite, and occasionally as small vein fillings.

The origin of the ore in its present form in the schist is undoubtedly due to the oxidation by surface waters of copper-bearing pyrite and chalcopyrite present in the schist, and a concentration by the same agency at a later time in the present enriched zone, partly by replacement of pyrite by chalcocite, and partly by deposition in crevices and along seams. The original source of the ore cannot be stated with any claim to certainty. Contemporaneous deposition of the copper-bearing minerals and the schist cannot be possible, as the bordering granite, a younger rock, carries the copper minerals in what is probably their original form. The same objection can be brought against the granite porphyry as a source of the copper, as, if that rock is distinct from the granite, it is certainly younger. The diabase present shows no evidence of having been the source of the ore. There are only two reasonable sources: the granite or mineralized solutions arising from an unknown source in depth. The granite carrying copper in proximity to the orebody is itself shattered, and it is along the seams caused by this shattering that the bulk of the pyrite and chalcopyrite occurs. Massive uncrushed blocks of granite are practically free from sulphides. This

would appear to indicate that the sulphides in the granite have been introduced since the cooling of the rock itself, and after several regional movements had shattered the already consolidated granite. Copper-bearing and iron-bearing waters arising from depth along the contact between the schist and granite and impregnating both rocks would appear, therefore, to be the most reasonable hypothetical source for the original sulphides. The schist, because of greater brittleness with consequent greater shattering, afforded more favorable ground for the circulation of surface waters, and the oxidizing and concentrating processes resulted from this water circulation.

## Two New Treatment Plants in Western Australia

By M. W. VON BERNEWITZ

The Mountain Queen mine near Southern Cross, and the Yuanmi mine in the East Murchison, recently started the treatment of ores in rather interesting plants, and through the courtesy of J. A. Agnew, of Bewick, Moreing & Co., I am able to give a sketch of the methods of treatment.

The published yields from these two mines for April were as follows:

	Mountain Queen.	Yuanmi.
Tonnage .....	3,735	4,280
Yield .....	\$17,200.00	\$43,700.00
Profit .....	\$5,600.00	\$20,400.00
Mining cost .....	\$1.20	\$4.32
Milling cost .....	\$1.06	
General cost .....	\$0.40	

The Mountain Queen has a set of double No. 1 Holman pneumatic stamps crushing the ore through 10 by 10-in.

PATENT PNEUMATIC OR AIR-CUSHION ORE-STAMP.

wire screens. These are the first pneumatic stamps at work in Western Australia, and I believe in Australia, though they are common in Cornwall, where they show a marked improvement in costs over the ordinary stamp. The pair under review crush from 135 to 160 tons of fairly hard ore per day, or 67 to 80 tons each. The speed is from 123 to 135 drops per minute, and, other things being equal, the pair is equal to a battery of fifteen 1250-lb. stamps. There has been no trouble with the patent gear, only the usual

battery repairs are necessary, and the wear and tear is about the same as with ordinary stamps. Mr. Degenhardt, the firm's engineer, informed me that for cost of erection and general upkeep, the Holman stamp is very satisfactory.

The air-cushion is produced in the following manner: In the walls of the cylinder are four rows of holes (see figure), two above and two below the centre position of the cylinder. Rows two and four are plugged. As the cylinder travels up and down, it traps the air between the piston and the cylinder covers, and the air thus compressed acts as a cushion, and on the return stroke assists in the propulsion of the stem. As the shoes and dies wear, the holes in rows two and four come into use, and rows one and three are plugged. By this patented device an equal distance is maintained between the shoe and die, for owing to the thinned 'air-cushion' being at the bottom of the cylinder, the piston, and consequently the shoe, is not raised as high as previously; a very considerable improvement on the old method. The following details are supplied by the manufacturers, and the weights given include steel framing:

Size.	No. 1.	No. 3.
Diameter of cylinder (in.).....	9½	6
Stroke (in.) .....	12	10
Power for stamp (hp.).....	25	15
Single stamp, weight of battery (tons)...	12¾	5¼
Double stamp, weight of battery (tons)...	21	8¾

The pulp from the stamps in the Mountain Queen plant passes to two 5-ft. grinding pans fitted with Freeman classifiers, in which classification is by segregation due to centrifugal force. The flow from the pans then passes over two copper plates, 12 by 6 ft., and in all, about 70% of the gold is recovered by amalgamation. The sand and slime flow to ponds, and will be treated later with the current mill product, by a new process, which is claimed to be of considerable interest. The plant described is driven by a 165-hp. Kynoch suction gas engine, which is powerful enough to drive the other plant being erected.

At the Yuanmi, the ore, after passing a jaw-breaker, is crushed by 20 Fraser & Chalmers 1250-lb. stamps, dropping 7½ in. 103 times per minute, at the rate of 8 tons per stamp daily through 10 by 10-in. screens. A larger screen, 10 by 12, is occasionally used, depending on the character of the ore, which, from some portions of the mine, is very hard. Crushing is done in weak cyanide solution, this coming from the treatment plant. The mine-water is fairly fresh, containing the usual magnesia salts found in our northern waters. The mortars have a band shrunk around the screen opening to prevent cracking at this weak point. In this mill there is no amalgamation.

The battery pulp flows to one leg of a Forwood-Down 10 by 48-in. sand pump, and is elevated about 12 ft. to a cone classifier, 6 ft. diam., the underflow going to a 16½ by 4-ft. Krupp tube-mill, working at 29 r.p.m. The overflow from the classifier, as well as the discharge from the tube-mill, goes to the other leg of the pump. This is raised to another cone, and the underflow, which consists of coarse sand, returns to the first leg of the pumps, and through the tube-mill. The tube-mill is fitted with the corrugated liners so popular in Western Australia now, and a great quantity of the pebbles used consists of hard ore from the mine. The overflow from No. 2 cone-settler gravitates to two continuous mechanical thickeners, the overflow of clear water being returned to the battery-supply tanks. The thick slime flows to three ordinary agitators, agitated with cyanide, and finally treated in a gravity-type vacuum-filter, similar to that described by Degenhardt and Stevens in the *Monthly Journal* of the Chamber of Mines, for March of last year. The residue, containing 27% moisture, is mixed with mine-water, and flows to a pond. The first 15 to 20 minutes wash from the filter is passed through vacuum clarifiers, and then to the precipitating boxes.

The whole plant is driven by 200-hp. Crossley suction gas engine, with low cost. The simplicity of the Yuanmi mill is at once apparent, as there seems a tendency in some mills at present to be as complex as possible.

## Midyear Spelter Statistics, 1912

**Production.**—Figures compiled by C. E. Siebenthal, of the United States Geological Survey, from reports by all zinc smelters operating during the first six months of 1912 and from the records of the Bureau of Statistics show that the production of spelter from domestic ore in that period was 159,952 short tons, and from foreign ore 6544 short tons, a total production of 166,496 tons of primary spelter, compared with 140,196 tons for the first half of 1911, and with 146,330 tons for the last half of 1911. This production for the first half of 1912 is at the rate of over 330,000 tons per year, more than double the production of any year prior to 1904 and approximately 46,000 tons greater than the production in 1911. The apparent consumption for the period was 159,046 short tons, as compared with 145,157 tons for the last half of 1911 and 134,902 tons for the first half of 1911. The stock of spelter held at smelters on June 30, 1912, was 6414 short tons, as against 9081 tons at the beginning of the year. This stock of spelter is in part made up of the ordinary working stocks at smelters, but also includes stocks of special grades of metal held for particular demands. The stocks are now smaller than at the close of any year since 1906.

	Jan. 1 to June 30, 1911.	July 1 to Dec. 31, 1911.	Jan. 1 to June 30, 1912.
<b>Supply:</b>			
Stock at beginning.....	23,232	17,788	9,081
Production—			
From domestic ore.....	135,061	136,560	159,952
From foreign ore.....	5,135	9,970	6,544
Imports.....	146	463	3,053
Total available.....	163,574	164,581	178,630
<b>Withdrawn.</b>			
Foreign exports.....	7,903	6,452	7,331
Domestic exports.....	2,981	3,891	5,839
Stock at close.....	17,788	9,081	6,414
Total withdrawn.....	28,672	19,424	19,584
Apparent consumption.....	134,902	145,157	159,046
<b>Spelter made in—</b>			
Illinois.....	41,255	41,875	44,224
Kansas.....	50,574	47,839	52,485
Oklahoma.....	19,997	26,318	36,010
All other States.....	28,370	30,298	33,777
	140,196	146,330	166,496
Zinc ore imported.....	37,885	38,097	27,049
Zinc content.....	15,028	17,112	12,228
Zinc ore exported.....	9,625	8,656	13,709

**Imports.**—The imports of zinc ore were 27,049 short tons, containing 12,228 tons of zinc, as compared with 38,097 tons of ore, containing 17,112 tons of zinc, in the last half of 1911, and 37,885 tons of ore, containing 15,028 tons of zinc, in the first half of 1911. Of the imports of zinc ore in 1912, about 95% came from Mexico, the remainder being credited to British Columbia and other countries. These figures are exclusive of lead ores from South America containing less than 13% of zinc. The exports of domestic zinc ore were 13,709 short tons.

**Smelter Capacity.**—At the beginning of the year the total capacity of the smelters reporting production for the first half of 1912 was 81,582 retorts, and the construction of 15,868 additional retorts was contemplated in 1912. At an annual average of  $4\frac{1}{4}$  tons per retort, the spelter capacity of the 81,582 retorts for the first six months would be 173,362 tons, less than 7000 tons in excess of the actual production of primary spelter. Taking into consideration the secondary materials, such as zinc drosses resmelted at the regular smelters, the large quantity of low-grade carbonates recently smelted, and the impossibility of operating continuously at maximum capacity, it is evident that the smelting capacity of the plants in operation has been strained to the utmost during the past six months, and that any added retorts must have been put into operation as fast as completed. The plants of the American Zinc Co. of Illinois and the R. H. Lanyon Zinc & Acid Co., both under construction at Hillsboro, Illinois, will go into operation with 5800 retorts between October 1 and the close of the year.

**Prices.**—Spelter started the year at 6.25c. per lb. at St. Louis, the minimum price for the first six months. The price

rapidly rose to 6.90c. by the middle of March, after which it quickly declined to 6.55c. per lb. in sympathy with a similar decline at London. By a steady climb through the remaining months of the period the lost ground was made up, and June closed with spelter at 7c., the average price for the six months being 6.65c. per lb. The London price opened at £26 15s. per long ton (5.78c. per lb.), remaining stationary for a time, but declined to £25 per long ton (5.41c. per lb.) by the latter part of March. The then market remained stationary at a little over 5.5c. until the close of June. The difference between the London and New York prices at the beginning of the period was 0.67c. per lb., and at the close of the period it was 1.43c. per lb. As the average New York price of spelter for January was but 0.79c. per lb. higher than the average London price for January, and as the duty on spelter is 1.375c. per lb., it is interesting to note that the Monthly Summary of the Bureau of Statistics for January gives the imports of spelter for that month as 4,377,360 pounds.

## The Thames Goldfield

From the year 1867 to 1911, the mines on the Thames goldfield, of New Zealand, have yielded over \$25,000,000. Among the chief producers were the Caledonian with \$10,000,000; Waitotahi, \$3,500,000; Kuranui, \$2,500,000; Queen of Beauty, \$1,850,000; Moanataiari, \$1,800,000; Golden Crown, \$1,750,000; Shotover, \$1,500,000; Cambria, \$1,050,000; Prince Imperial, \$1,000,000; and Long Drive, \$870,000. The future of the field depends on results from the deep-level work now in progress. The drift from the 1000-ft. level of the Queen of Beauty shaft is now out 2100 ft. in Waitotahi property, which yielded rich ore a few years ago. About \$87,000 has been subscribed for driving this level, and subsequent prospecting. The shaft mentioned is equipped with a large horizontal-gear pump engine, which drains the whole field, the present flow being 600 gal. per minute. The New Zealand Government owns this plant and assists the work in progress. Several lodes have already been cut, and are being opened. Local opinion is divided as to the value of this deep-level prospecting. A good deal of diamond-drilling has been done in the past, with much trouble and disappointing results. Apart from the present work, a number of claims are being developed, and about 6000 tons is treated annually. The population of the district totals some 5000 people. The old-established foundry of Price Brothers, which has specialized in mining machinery, is now busily engaged constructing large locomotives for the New Zealand Government. About 190 men are employed and a new engine steams out every 30 days or so. The Thames district will eventually depend on agricultural pursuits, as the surrounding plains are rich for dairying, sheep, fruit, and vegetables. The fishing industry is being extended, the gulf being exceptionally prolific in all edible fish.

SULPHUR is found in Utah, and the deposit has been recently described in a report (Bull. 530-O) issued by the U. S. Geological Survey. The deposit lies in the south-eastern part of the state, in the canyon of the San Rafael river, 18 or 20 miles west of the town of Greenriver. At the point where the sulphur occurs the canyon widens until its floor is probably a quarter of a mile across. As the spot is approached in coming up the canyon the existence of sulphurous springs is indicated a mile or more away by the odor of hydrogen sulphide, possibly more because the spring water has mingled with that of the river than because the gas has been carried so far by the breeze. A strip of rock debris about 100 or 150 ft. wide by 750 ft. long is impregnated with sulphur which has been formed from the gas in the springs, and while there is no doubt that sulphur can be extracted, the scarcity of fuel, an 18 or 20-mile haul to the railroad, and a restricted market, make it unlikely that the deposits can be worked at present at much profit.

## Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

### Drilling Contest Records

The Editor:

Sir—In an editorial note in your issue of July 13 you say that Page and Pickens established a new record in a drilling contest at Tonopah by drilling 45 7/16 inches in Rocklin granite. I should like to call your attention to the fact that at a contest held here in Colorado Springs at the time of our Quarto-Centennial Celebration in August 1901, this record was surpassed by Stewart and Carmack, of Leadville, who drilled 46 inches in 14 1/2 minutes. If I remember correctly, the reason they stopped half a minute before the full time was out, was because they had drilled through the block of Gunnison granite provided for the contest. According to contemporary newspaper accounts, the record previous to this was 39 1/2 inches, which was broken by three teams in addition to that mentioned above. Hupps and Lindquist, of Ouray, drilled 43 3/8 inches; Chamberlin and Malley, of Leadville, 41 1/4 inches, and McNichols and Lamb, of Victor, 40 1/8 inches.

HORACE F. LUNT.

Colorado Springs, July 20.

### Gilpin County Ores and Their Recovery

The Editor:

Sir—I am sorry to see that the *Mining and Scientific Press*, in its issue of July 6, lends the weight of its authority to support the statements that "the tailing losses (in the treatment of Gilpin county ores) have been heavy; much heavier than was generally realized or admitted"—a statement which, applied indiscriminately, has been the cause of much harm to the spread of sound ideas for the improvement of Gilpin county metallurgy.

It is not the fact that the savings have uniformly been low; on the contrary, the saving by amalgamation and subsequent concentration on such ores as those of the Gunnell and California mines has been remarkably high. Such ores have contributed at least two-thirds of the entire production of the district in the past, and will probably continue to do so in the future. I do not say that there is no possibility of improvement by the use of cyanide; but every metallurgist who has investigated the subject has found that there is a rather depressingly small margin to work on. Another large class of ores in the district yields good recoveries by simple concentration, with the drawback that the concentration ratio is often low, and the ultimate cost of smelting the concentrate necessarily high, figured back on the original ore.

There remains a class of ores, at once varied and complex, on which no milling method has yet proved successful, and this forms a virgin field for the exertions of our cyaniding friends. Unfortunately, all experiments hitherto have indicated that such ores are no more docile to cyanide treatment than to other simple processes; and they remain a problem, or problems, to which as yet we have no satisfactory solution, except the expensive one of smelting.

The real difficulties in Gilpin county metallurgy, as a whole, centre in the fact that the orebodies are exceedingly varied from a metallurgical point of view, and usually relatively small, so that one has often no sooner worked out the best possible method of treatment for any particular kind of ore than that ore is exhausted, to be succeeded perhaps by a different type. It follows that Gilpin county metallurgy must always necessarily consist of compromises, a mill being designed to give the best commercial result

on a variety of ores, rather than the best possible result on a single ore. For a large class of ores, simple amalgamation and concentration remain today the best standard method of treatment, and simple concentration for another large class. If there is to be a single method of treatment commercially applicable to all ores, it will have to be something which is not in sight today.

GEORGE E. COLLINS.

Denver, Colorado, July 20.

### Specific Gravity Chart

The Editor:

Sir—Frequently in cyanidation, when slime is being handled, the percentage of moisture and the percentage of solids in pulp must be known in order to determine the proper treatment. The common practice is to determine their quantities from the specific gravity determinations,

SPECIFIC GRAVITY CHART.

which are taken at frequent intervals during the day. Most moisture percentage charts involve curves and are to a certain extent puzzling. They are constructed by using an algebraic equation and are not easily made. The chart here illustrated is easily made and is clear and correct. It can be made in a few minutes, and with much more detail than shown in the sketch.

The chart is made by using coordinates. The ore in this case has a specific gravity of 2.65. On OY lay off OB, which represents a specific gravity of 1 and which will be the specific gravity when the agitator, or whatever the receptacle containing the pulp, is full of water. Using

the same scale, lay off OA on OX, representing the specific gravity of the receptacle when full of solids or ore. This quantity is 2.65. Now the line AB represents all specific gravities ranging from 1 to 2.65. Any intermediate specific gravity lines such as those shown on the chart may be found by dividing this line AB into 16.5 equal parts. (The difference between 2.65 and 1 is 1.65, and the lines on the chart represent one-tenth of 1%, therefore divide by 16.5 instead of 1.65 to get the division, such as BD on the chart). An equation containing two variables whose sum equals a constant is represented by a straight line 45° to the ordinate. This is the case of the two variables, percentage of moisture and percentage of solid, the sum of which is always 100%. Let this line be any such line as BC, and let the specific gravity lines cut BC. To read this chart, find the point where the line representing the specific gravity already determined cuts the line BC. Reading directly across from this point to the side scale will give the percentage of solids; directly down will give the percentage of moisture.

This chart can be changed to one for a pulp having an ore of different specific gravity than 2.65. In that case let OA on OX represent this new specific gravity in the same scale with OB.

GEORGE B. McLAIN.

Tom Reed Mine, Oatman, Arizona, July 1.

### Zinc-Dust Precipitation

The Editor:

Sir—Errors of mill construction materialize when the operator is unable to obtain the results expected by the designer. Errors of detail become more serious as the run continues, and their cause generally proves to be the neglect of the constructing engineer, who has followed the so-called 'general mill plans' too closely, instead of consulting the installation prints of apparatus supplied by inventors and patentees.

One of my most recent experiences was in Arizona. The Merrill zinc-dust precipitation process was installed at the time of constructing the mill. Some curious non-results were obtained during the first attempts at precipitation. An inexperienced operator performed the operations as outlined and as universally adopted. Samples of the incoming pregnant and barren effluent solution assayed the same, indicating absolutely no precipitation of the precious metals. A close regeneration was not expected from the weak NaCN solutions with little protective alkali containing an extremely small gold content, due to the adoption of the decantation methods before the completion of the vacuum-filter. But certainly some press extraction was anticipated even under these conditions. Laboratory tests resulted in the precipitation of the metals from the solutions with a longer contact than the installation would allow before reaching the filtering medium. The Bosqui dust-feeder and tank apparatus seemed a necessity. After these tests I inspected the plant, finding that a pressure of over 25 lb. showed on the gauge with the press filtering at but 50% of its rated efficiency. The filtering medium was light twill, but it was evident that the press was getting an oversupply of air, as the solution coming from the spigots was foaming and bubbling. The air-connection to the press was evidently closed, and at first I thought the pump was taking air at the plungers, until noting the arrangement of piping and position of valves. In connecting up the 5 by 7 triplex electric pump supplying the press, a by-pass was neglected, and the valve on the pump suction was placed on the tank side of the zinc-dust feed-pipe. This valve was used in regulating the press flow and pressure, and naturally the pump took an enormous amount of air from the dust feed-pipe.

To overcome these errors and to lengthen the contact of the zinc with the solution, a return by-pass pipe was extended from a point near the press to the suction of the pump. A valve was placed on this line near the press to regulate the flow and pressure to the press, and a check-

valve was put on the suction between the return pipe and dust feed-pipe to check the return of solution to the tank. Thus the circulation of dust and solution before filtration was secured. Results were obtained immediately after these changes, and the press was brought to a high efficiency. It seems obvious to me that by installing a pump of greater capacity than the press, with the use of this return pipe, increasing the velocity and friction within the supply pipe, the danger of precipitate accumulation within the pipes would be lessened and the agitation and longer contact beneficial, in some cases doing away with the Bosqui tank and feeder installation. In this case, zinc-shaving boxes were ordered to replace the dust apparatus by the local mine manager, of South African experience. The order did not pass the main office immediately, so the unnecessary expense was avoided. Think of the enormous bulk of zinc-shaving necessary for the precipitation of 250 tons per day of 50e. solution, and the \$4000 or \$5000 gold absorption, compared with the simplicity of the zinc-dust appliances.

E. S. PETTIS.

Mill Valley, California, July 11.

### The American Institute of Mining Engineers

The Editor:

Sir—As the report of the Committee of Five has now been published, a discussion by the members of the American Institute of Mining Engineers between now and the next meeting might be of value in enabling a proper decision to be made at that time regarding a future policy.

I would call your attention to one peculiar misprint on the sixth line from the bottom of page 11, where the word 'perpetuated' must be wrong. Probably the Committee wished to say perpetrated. I would be very sorry to see the Institute increase the annual subscription for two reasons: one is that \$10 is enough; by way of contrast I may mention that I pay \$12.50 to the Institution of Civil Engineers and get four volumes of transactions annually. The other reason is that, from my acquaintance with the younger members of the Institute, I am satisfied that many cannot afford to pay \$15 annually, and many of them will drop out.

Our organization is face to face with a serious problem, and its solution must be along the lines of elevating the character of the Institute in every direction. The Institute has never been ultra-professional, and it is probably better so. At the same time, subjects such as the formation of local branches throughout the country; the discussion of improved mineral and mining laws; keeping members posted regarding recent advances in mining and metallurgical methods; the preservation of the health and lives of those engaged in the mining industries; the financial aspects of mining operations; and the standardization of mining technology have never received sufficient attention. Only by elevating the general standards of the Institute will its true growth be made. The ownership of a half million dollar equity in the United Engineering building no doubt dignifies our New York headquarters, but this equity will never take the place of the standards which the Institute is organized to maintain and on the maintenance of which its whole future existence depends.

The Institute, like the Republic of Mexico, is suffering today from reactionary management; and the present difficulties must be solved, in a new and progressive spirit. The acquirement of more money is not in reality the vital need of the Institute today in spite of the pressing nature of its financial problems.

JAMES W. MALCOLMSON.

Kansas City, Missouri, July 24.

[We heartily endorse Mr. Malcolmson's statement that "money is not in reality the vital need of the Institute today." Service is more necessary than money, and this should be the intelligent service of the whole membership rather than that of the few.—EDITOR.]

## Special Correspondence

### BUTTE, MONTANA

JULY PAYROLL OF BUTTE MINES.—REPORT OF STEWART MINING CO.—NEW COMPANIES TO OPERATE IN DISTRICT.

The payroll of the mines of Butte for the month of July shows that the Anaconda company alone will pay out about \$1,163,000 and that the total for all the mines of the district will amount to fully \$1,500,000. Through the increase in wages granted the miners by the Anaconda company alone, the payroll will be increased in a year by at least \$1,500,000, and the total increase in the district will be close to \$2,250,000. As long as copper remains above 17c. per pound the payroll of this district will be about \$18,000,000 per year. With this amount for labor is not considered the sum the Anaconda company is spending in placing the compressed air system and the underground electric haulage system at the different mines. The controversy between the East Butte Mining Co. and the miners' union over the wage-scale agreement was settled without friction after Oscar Rohn, manager for the company, realized the fact that the smeltermen working in this city were under the direct supervision of the miners' union since the mill and smeltermen's union was disbanded. Mr. Rohn sent the miners' union a letter notifying the organization that he would see to it that the smeltermen employed by the company would receive for June and July in their August checks the amount of the shortage for these months. The report of the Stewart Mining Co. shows that the net earnings for the first six months of the year ran over \$200,000. The month of May was the record when the net earnings were \$49,800, after charging \$12,800 to development and construction. According to a statement given out, the company could well afford to pay a dividend, but in consequence of the application for a receiver and an accounting, nothing will be done in this direction. The Stewart is treating 500 tons of ore per day. The delays which have occurred in the hearing of the application for a receiver are having a discouraging effect on the stock.

The quarterly report of the North Butte Mining Co. shows that a large amount of new ore has been opened in the property farthest north. The 2200-ft. level of the Snowball vein has been advanced over 200 ft. west and shows continuous ore which averages 5 ft. wide, assaying 8% copper and 19 oz. silver per ton. The east drift shows 40 ft. of ore averaging 5 ft. wide, assaying 5% copper and 10 oz. silver per ton.

The Davis-Daly company is shipping 10 cars or about 500 tons of ore to the smelter per week. This ore contains about 6% copper and the returns for the past two months have more than paid the operating cost. The orebodies opened on the 1900-ft. level west cross-cut are encouraging. The cross-cut is now about 280 ft. from the shaft and it is estimated that the main vein, which was opened up on the 1700-ft. level, will be reached in the course of another week. The management will develop this level before sinking deeper.

The Tramway mine, which has been closed for two months while the hoisting engine was equipped with new cylinders for operating by compressed air, is now in commission. The Pennsylvania plant will be the next one to be changed over for air. The Nordberg Manufacturing Co. of Milwaukee, which has the contract for making the changes required, estimates that the entire work of equipping all the engines of the Anaconda company will be completed in another year. At the Mountain View mine, underground electric haulage will be in use in another month. All the claims in the northern part of the district have either been purchased or are held under options as a result of the recent boom in Butte & Superior. At least three new companies are expected to commence operations soon. A boom in the stock of Butte & London, which carried the price from 10c. to 95c. per share, followed the rumor that the Butte &

Superior company was prepared to back the reopening of this property.

The Hidden Lake, one of the richest gold-producing properties in the district south of Anaconda, is likely to pass into the hands of New York and English capitalists. An option for sixty days was secured on the property some time ago and this option expired, and a day or two before the expiration an extension of thirty days was conceded. It is stated that the only reason for the extension of time was the death of an interested party which made it necessary to change some of the plans in regard to financial arrangements. The ore being hoisted from the mine runs from \$16 to \$35 per ton in gold with a fair percentage of copper. A vein 8 ft. wide was opened which is very rich. The property consists of 16 claims, and it is understood that the option calls for the payment of \$1 per share on the 300,000 shares outstanding. All the stock is held by Butte and Anaconda people. The property is situated within two miles of the extension of the Butte, Anaconda & Pacific railway.

### TORONTO, CANADA

PORCUPINE STOCKS DECLINE ON LACK OF OFFICIAL REPORTS.

—PROGRESS AT THE MINES.—RECORD SHIPMENT OF BULLION FROM COBALT.

In spite of highly favorable reports of the operations of the Porcupine mills which appear from time to time with correspondingly optimistic estimates of the output, the share market continues to show a downward tendency to an extent not altogether accounted for the usual mid-summer slackness. The cause is probably the entire absence of any official statements as to the actual output, and the reluctance of the public to accept general figures, which may be based on guesswork. It is stated that the results so far obtained prove that the ore is free milling and the extraction high, and that average returns will run over \$10 per ton, all of which may be taken for what it is worth as the views of those on the spot who are endeavoring to size up the situation. The average daily tonnage of ore treated at the Dome is calculated at 335 tons, and at the Hollinger 300 tons. It is understood that the former company contemplates adding 20 or 30 stamps. At the Dome mine the 100-ft. level will shortly be connected with the incline up which the ore-cars run to the mill. A body of high-grade ore recently found on this level will considerably increase the average quality of the ore treated. The main workings will be connected with the shaft sunk near the Golden Stairway vein, which is to be put down to the 400-ft. level. The McIntyre has made its second payment of \$50,000 on the property, and only a comparatively small amount now remains to be paid. The Hollinger Reserve property is being steadily worked. The main shaft is down 100 ft., and three good veins averaging 4 to 5 ft. wide have been tapped in cross-cutting. At the Dome Lake four shafts are being sunk, two of which are down 170 ft. They will be connected at the 100-ft. level, where a large body of ore will be blocked out. The richest vein is from 5 to 6 ft. wide and has been stripped for 800 ft., samples showing an average of \$28 per ton. The Preston East Dome, which has been working the East Dome claim since it abandoned the Preston, has decided on discontinuing operations, there being apparently little chance of success. C. A. Foster, of Haileybury, has taken an option on the Tough-Oak claims in the Swastika district, about six miles north of the Swastika camp, where there is good ore occurring in a porphyry dike averaging 15 ft. in width. Amalgamation is to be adopted at the Swastika, and should conditions warrant it later, cyanidation will be added. Foundations are being prepared for the mill, which will have a capacity of about 60 tons per day. At the Lucky Cross, in the Swastika district, a new vein recently found has widened to 5 ft. of rich ore. Good milling ore is being taken out in several places.

A new record for bullion shipments from the Cobalt

district was made for the week ended July 19, when a total of 153,882 oz. of silver was shipped, this being 30,000 oz. in excess of any previous week's shipments. The Nipissing was a long way at the head of the list with 120,158 oz. The Dominion Reduction Co., which is now operating the Nova Scotia mill, made its first consignment of 23,603 oz. from Crown Reserve ore. The total dividends paid by Cobalt companies for the first six months of the year amounted to \$3,578,399. The Crown Reserve, with the payment of its last declared dividend, will have returned to its shareholders 245% on its capitalization. The McKinley-Darragh has produced 1,530,000 oz. silver during the first six months of 1912. Work has been started on the building of the aerial tramway, 5000 ft. in length, by which ore will be brought from the Savage property to the McKinley mill. The Rochester is endeavoring to raise funds to continue development by organizing a holding company capitalized at \$1,000,000, which will take over existing stock, giving shareholders one new share for every four of old stock, and selling the remainder of the new issue. The Right of Way has abandoned its option on several claims in the Silver Mountain district near Port Arthur. The court at North Bay has sent to jail three 'high-graders', convicted of robbing the Timiskaming mine, who were cleverly caught by George P. Williams, a Pinkerton detective engaged by the Mine Managers' Association. He posed as manager of a moving-picture show, ingratiated himself with the suspected men, and became their partner. The sentences of the men were for terms of 9, 13, and 14 months imprisonment.

### LONDON

WAIHI AND ESPERANZA WILL LOOK FOR NEW MINES.—REPORT OF ZINC CORPORATION.—EXAMINATION OF COAL BY X-RAYS.

Two gold mines which have yielded large profits to English shareholders are the Waihi in New Zealand and the Esperanza at El Oro, Mexico. Both are now showing signs of exhaustion in depth and the directors of both companies are proposing to allocate some of the reserve funds in acquiring other properties. The Waihi yielded £9,785,431 from 1890 to 1911, inclusive; adding the output to June 2, 1912, when the strike suspended operations, the total is £9,990,833. The Waihi Gold Mining Co., Ltd., has paid £4,230,585 in dividends free of income tax, so that the money returned to shareholders represents 42% of the gross output in gold and silver. This has come from 4,057,700 tons; hence the average yield has been 48s. per ton, and the dividends 20s. 10d. per ton. Yet this mine that has yielded ten million sterling in precious metals was originally purchased for £3000. The capital of the company is 500,000 shares of £1 each; these reached a maximum price of £5 8s. 9d. in the early part of 1911, and are now quoted at £1 15s. The Esperanza mine is owned by a company organized in 1903 to acquire a mine in Mexico originally located in 1890 and opened up by August Sahlberg. The mine was a disappointment until 1895; and even then it did not do anything wonderful. The big bonanza was discovered by a drill-hole on the fourth level during October 1904, just a year after the transfer of the property to an Anglo-American company controlled by the Guggenheim Exploration Co. In 1906 the output of the mine attained its maximum, 207,182 tons, yielding £15,357,690. The biggest dividends were paid in 1906, the total amount distributed in England in that year being £728,000. Altogether from 1895 to May 31, 1912, the mine has produced 2,015,125 short tons of ore, yielding £6,170,200 in gold and silver, and profits estimated at £2,386,000. The price paid by the company was £450,000. The English subsidiary company, now in control, is capitalized for £455,000 in £1 shares, and has paid £2,331,875 in dividends. This mine is 1600 ft. deep and still has some ore in sight on a new vein called the San Carlos. The Waihi is 1261 ft. deep, and it is proposed to sink the shaft whenever troubles from

water and labor are overcome. The end of the Great Boulder Proprietary company operating the gold mine at Kalgoorlie appears also to be within measurable distance, for the main orebody has passed out of the boundary into that of the Golden Horse-Shoe between the 2650 and 2800-ft. levels, and the prospecting and development during the past year in other parts of the property have not been promising. The ore reserve on December 31 was estimated by Richard Hamilton, the manager, at 698,662 long tons, averaging 14½ dwt., which should provide another million pounds in dividends spread over four years. During 1911 187,510 long tons of ore was raised and treated, yielding 158,351 oz. bullion, worth £567,639. The working profit was £306,829, out of which £29,855 was paid as taxes, £14,000 written off for depreciation, and £262,500 distributed as dividend, being at the rate of 150%. This company has hitherto been a most regular producer. The first year, 1895, yielded gold worth £107,023, and during the next seven years the output steadily grew. From 1903 onward the yearly production has been practically constant.

A consolidation was made in London on July 8, 1911, of the Zinc Corporation and the Broken Hill South Blocks, two companies registered in Victoria, Australia. The for-

ZINC CORPORATION WORKS, BROKEN HILL.

mer company had been treating zinc tailing at Broken Hill since 1905 and producing zinc and lead concentrates, at first by the Elmore vacuum plant, and since the end of 1910 by the Minerals Separation process. The South Blocks company owned a mine containing two lodes, one of which is higher in zinc than lead. The issued capital of the new company was 245,692 preference shares of £1 each and 653,139 ordinary shares of 10s. each. Of these, 179,026 preference shares and 453,132 ordinary shares were allotted to the shareholders in the old Zinc Corporation, and 66,666 preference shares and 200,000 ordinary shares to the shareholders in the South Blocks. A report recently issued covers the 5¾ months from the date of registration to the end of 1911. It was desirable to make the company's financial year coincide with the calendar year, as the final settlement of zinc prices is made on the basis of the average price during a calendar year. Special arrangements have had to be made on this account to enable a dividend to be paid on the ordinary shares for the short period under review. During this period, 140,370 tons of tailing drawn from eight separate dumps was treated in the flotation plant, and the yield was 42,350 tons of zinc concentrate, assaying 45.3% zinc, 7.7% lead, and 13.9 oz. silver, and 3865 tons of lead concentrate, assaying 55.3% lead, 16.4% zinc, and 34.4 oz. silver. In addition, 3988 tons of slime assaying 38.6% zinc, 13.2% lead, and 23.4 oz. silver has been dumped for further treatment. At the mine 64,313 tons of ore was raised and treated in the lead mill, yielding 11,846 tons of lead concentrate averaging 64.9% lead and 8.7 oz. silver; also 16,315 tons of zinc tailing, which was sent to the flotation plant. The income from the sale of concentrates and sulphuric acid was £235,661, this being subject to adjustment when the average price of zinc during 1912 has been ascertained, and the net divisible profit was £73,243. Accompanying the directors' report is one by Theodore J. Hoover, who recently made an examination of the mine and the plant. He estimates the ore reserve at the mine at 665,000 tons, averaging 14.6% lead, 9.4% zinc, and 2.3 oz.

silver. This does not include the lode which is higher in zinc, as that has not been sufficiently developed to warrant an exact estimate, though Mr. Hoover gives a preliminary estimate of 300,000 tons averaging 19% zinc, 8.5% lead, and 1.5 oz. silver.

At a recent meeting of the North of England Institute of Mining and Mechanical Engineers, F. C. Garrett and R. C. Burton read a paper describing their experiments with X-rays for the examination of coal. Coming so soon after James Lomax's paper on the examination of coal by means of the microscope, this paper created unusual interest. The carbon and organic parts of coal are much more transparent to X-rays than the mineral constituents which subsequently form the ash, so that an examination by radiography indicates the presence and distribution of the mineral substances. It is possible in this way to get an idea of the value of the coal from the point of view of ash, and by observing the size of the shadows to estimate whether the mineral can be removed by washing. The authors publish many radiographs of various coals, and of these, one of the most interesting is that of the Victoria-seam coal from Durham. The ash of this coal amounts to only 1¼%. The coal on examination exhibits a columnar structure, and the authors connect this structure with the characteristic of being a good coking coal, though several speakers at the meeting expressed a doubt as to the connection. The authors also state that the X-rays serve to differentiate certain minerals such as calcite and pyrite. Though the paper only gives the results of a tentative series of experiments, it opens up an important field of research.

## BOSTON

### INFLUENCE OF ZINC MINING ON THE BOSTON MARKET.—

LABOR PROBLEM AFFECTS LAKE COPPERS.—ELECTRIFICATION OF BOSTON & PROVIDENCE RAILROAD LINE.

From the Boston standpoint, zinc has been, until recently, a metal which stood at the foot of the list, commercially as well as alphabetically. The importance of zinc ore development in the northern end of the Butte district, and the record high price of spelter—7.3c. per pound, New York delivery—has changed the situation. Now all Butte stocks are in demand, especially as the smaller companies, such as the Butte & London and the Raven, which were unsuccessful in their search for copper, are to be refinanced in the hope of finding zinc ore. The Butte Central Copper Co. reports that the framework of the concentrator is completed, and the officials expect the first two units to be in operation within 60 days. Cross-cutting has been started from the 1000-ft. level to reach the Rarus fault-zone, which is believed to be 200 to 400 ft. from the shaft. The management expects to find large copper orebodies in the fault-zone. The shortage in the labor situation in the Lake country is handicapping drilling and exploration at present, although there is activity in Superior, Isle Royal, and Houghton, due to promising lode development. At one time Boston would not become enthusiastic over any mining boom except those originating in the Lake country. This is now changed, although Cobalt and Porcupine stocks have never been handled here to any extent. Calumet & Hecla, while keeping up its copper production, has poured out a large part of its enormous surplus into investments in other mining companies along the Lake peninsula. Recently the company announced that it will retire \$1,000,000 in notes, thereby having paid off \$2,700,000 out of the issue of \$8,519,000 in notes which it gave in part payment for the Bigelow securities. Having retired \$2,700,000 of the notes, the company saves \$135,000 per year in interest charges. Calumet & Hecla had hoped to force production and complete the first half of this year with a substantially increased production over the corresponding period of 1911. But the labor situation held up the company's plans, and it not only affected Calumet & Hecla itself, but its various

subsidiaries as well. The chances, therefore, of taking full advantage of the present high price for copper metal have failed now of materialization, as far as the Lake Superior companies are concerned. The output record of the several Calumet & Hecla properties for the first six months of 1912, as compared with the first half-year of 1911, presents a very interesting situation. In the eight properties going to make the comparison (Calumet & Hecla, Ahmeek, Osceola, Tamarack, Isle Royale, Allouez, Superior, and Centennial) there were recorded four losses and an equal number of gains. Ahmeek, Isle Royale, Superior, and Centennial recorded the gains. Ahmeek and Isle Royale primarily have been the properties to push forward. Ahmeek has made a remarkable dividend record in the past two years, while Isle Royale, considered for years as a failure, and later as a slightly successful prospect, is now rounding out to that point where dividends are expected before another six months have passed into history. Mohawk is another of the Lake properties which is being closely watched here. Definite action is now going forward to make the company secure against possible low water, which so handicapped the company last year. Mohawk is fast accumulating a substantial surplus above its ordinary treasury surplus, and rumors once again are current that the company, at its next dividend declaration period, will advance the dividend rate.

There is some talk now that Wolverine, which does not take semi-annual dividend action until October, will restore the old rate of \$5 per share for the six months, or \$10 per share per year. Wolverine is making larger recoveries from its ore than at any time since February, while its output in June was the heaviest for the year past, with the exception of last October. The output for the year from July to July falls about 200,000 lb. under that for the previous fiscal year, but low production costs and high metal prices are making for better earnings. Developments at Wolverine have not been encouraging, and the company is slow in making acquisition of territory, though its property is believed to have reached that point where prolongation of life should be taken up from the standpoint of buying new ground. Wolverine was at one time the lowest-cost producer in the world, but its glory has in a measure waned.

Boston is much interested now in the labor problem of the Lake mines, principally because it affects the local issues from that district. Among those now threatened particularly are the Isle Royale, Calumet & Hecla, Osceola Consolidated, Franklin, Mass Mining, and Superior properties. Franklin has been forced to shut down for several weeks, but is now in a position to start again. Isle Royale has taken a squad of 500 men from points around Boston and shipped them to Michigan.

Followers of copper are interested in railroad electrification at Boston. The New Haven will electrify and four-track the Boston & Providence line for 42 miles out. This will be similar to the electrification of the Mellen system between New York and New Haven. This first actual piece of steam railroad electrification out of Boston is promised at an early date. It will call for a considerable amount of copper and will be a great help in influencing sentiment in behalf of railroad electrification generally. As soon as such electrification has been extensively entered upon, it is believed that copper will be pegged around 17 or 18c. per pound. At this price the metal is not considered to be prohibitory. All things are relative, and the high cost of commodities admits of a higher price for copper. A recent debate in the United States Senate over the building of the new custom house in Boston brought out the point that copper now might be too expensive to put into the building according to the original specifications. Copper is now on the verge of selling at a price which will automatically displace the metal in a great deal of construction and manufacturing plans. But the present price, everything considered, is regarded as conservative and consistent with the higher prices which commodities are commanding.

## NEW YORK

REVIVAL OF MINING INTEREST AWAITS RESTORATION OF TRANQUILLITY IN MEXICO.—PRODUCTION OF GUGGENHEIM COPPER COMPANIES FOR HALF-YEAR.

Mining interest in and about New York will hardly experience a general revival until perfect tranquillity is restored in Mexico. There is some sporadic, though largely professional, interest in the Tonopah district, where real mining progress has been made during the past few months. For a long time Mexico suffered by reason of the unduly low price of silver, and unfortunately just at the time when a real advance in the silver market would have placed many of the mines on a paying basis, the Diaz regime passed out and disordered conditions, prevailing since, have rendered impossible the enlisting of new capital in mining enterprises. There has been some progress made in the oilfields in and around Tampico, but the real uplift for Mexico will come when it is in a position to take advantage of the silver market. Statisticians figure that one-third of the world's present supply of silver was mined in Mexico, and present prices will undoubtedly prove an immense stimulus to production. It is remarkable to state that mining properties came through the revolution—if it may be so called—without any particular damage, and so soon as commercial progress is once more in full swing, mining can take up its part without having any serious damages to repair. Promoters with Mexican properties in which to interest capital are now not backward in proclaiming the fact that they can secure better results throughout the West in the United States than they can in Wall Street. The claim is made by many of them that it is not so difficult to place a property in Wall Street as it is to have anything left for themselves or the former owners after it has been so placed. The Englishmen who have had a hand in developing the properties at El Oro, which includes Esperanza and others, and the Camp Bird company which is now in control of the Santa Gertrudis, have probably a larger number of contented adherents throughout the United States than have any American promoters who have been successful in Mexico. If some American promoters could become imbued with English methods, it would greatly benefit the mining industry.

As a leading member of the Guggenheim family of porphyry coppers, the output of Utah Copper is very naturally something of an index as to copper production. The complete figures for the half-year are just available, and expectations of a record output are met with disappointment. The yield in May was 10,163,336 lb. With like figures for June, there would have been justification for those who have been talking much of increase in copper output. The figures for June, however, were just about equal to those of April, when the output was a little above 9,000,000 lb. The half-year showed a total copper production of 53,301,379 lb., some 7,000,000 lb. more than the corresponding period of last year, and 10,000,000 lb. greater than the production for the first six months of 1910. Utah Copper can produce a considerably larger volume of copper than is shown by these figures. The Arthur and Magna mills are capable of turning out 140,000,000 lb. of copper per year if conditions are favorable. At a property such as Utah Copper, temperature has much more to do with the volume of output than in smaller or deep-level mines. Severe stress of winter weather renders difficult the breaking down and shipping of ore to the mills, and intense heat makes it impossible to run concentrators and furnaces at full capacity during a 24-hour day. In other words, the human factor plays no inconsiderable part in the operation of so large a property, even though the ore is so largely handled by automatic machinery. It is quite evident that the Nevada Consolidated mine and the smelter at Steptoe are not being oper-

ated at capacity. The June production was 6,000,000 lb., in round numbers, but smaller than any month during the half-year, except February, when the output was less than 5,000,000 lb. The total output for the half-year was 35,670,457 lb., giving the Utah and Nevada a combined production of nearly 90,000,000 lb., or at about the rate of 180,000,000 lb. of copper annually. The Ray and Chino, Guggenheim properties, are making rapid progress. Ray has already climbed up to the predicted mark of 3,000,000 lb. of copper per month, and while extraction at first ran but 59%, the mill management now reports average extraction of 70%. While Chino operations are not so far along, its progress is proportionately as rapid. As to dividends, there is considerable market capital made out of the possibilities of an increase in the rate of the Nevada Consolidated. It is stated semi-officially this week by one of the directors that the dividend will not be increased next month, though, if metal-market prices are maintained, some such action may be taken in November. This practically precludes the possibility of an increase on the part of Utah Copper, as one-half of the Nevada disbursements go into the Utah Copper treasury. Greene-Cananea Copper Co. has been placed upon a quarterly dividend basis, and disbursements will be made hereafter in March, June, September, and December. This move amounts to an in-

NEVADA CONSOLIDATED MILL.

crease in the dividend from 50c. to \$1 per year. The Yukon Gold Co. reports by cable from Dawson a most satisfactory half-year. Operations to June 30 showed 1,460,400 cu. yd. dredged, against 1,773,917 cu. yd. up to the same date in 1911, with, however, an average recovery per yard of 76c. as against 55c. last year. The bullion output is \$1,116,700, as compared with \$654,668 last year.

The reorganization committee of the Nevada Utah Mines & Smelters Corporation has acquired title to that part of the property in which the old company retained an ownership by reason of the confirmation of a sale made by a referee in the United States District Court. All of the stockholders are to be asked to come in on the same terms as those who originally subscribed to the reorganization committee plans. The move of F. Augustus Heinze to 'sidetrack' the litigation brought by the stockholders of the Stewart Mining Co. by transferring the suit to the federal courts has failed. The stockholders originally filed their suit in the state courts in Idaho, claiming that the funds of the Stewart Mining Co. were being and had been diverted to the use of the Ohio Copper Co. and asking for a receiver and other relief. Heinze's application to transfer the suit has been denied, and the state courts will now handle the entire matter. The New York stockholders are trying to form a protective committee to secure a proper administration of the mine and mill. The interests that are opposing Heinze, claim that since the restraining order was first made by the local courts the company has been making about \$35,000 per month on a much smaller output than was being produced by Heinze.

## General Mining News

### ALASKA

#### COPPER RIVER

At the Nugget creek property of the Alaska Consolidated Copper Co. the bornite vein has been reached by the 200-ft. level, and cross-cutting shows it to be as rich as in the upper level. It is expected that development will open enough ore to supply a large concentrating plant. It is hoped to get the pumping and hoisting plant to Strelina in time to be brought to the claim, over the first snow. The Rarus has an iron outcrop over 400 ft. wide in a contact between lime and conglomerate. The surface is decomposed and copper stained. It is expected that the mine will be an active producer next winter. A. B. Iles is manager.

The Silverman Syndicate mines, at Falls Creek, got \$1700 from 79 tons of ore. The mill will eventually consist of a Nissen stamp, crushing through 40-mesh screen, a Chilean mill for regrinding, and cyanide plant.

#### JUNEAU

The Alaska Treadwell operations for June may be summarized as follows: The 240 and 300-stamp mills worked 29.6 days, crushing 33,012 and 49,168 tons respectively. The estimated gross value of the free gold was \$107,152, while the 1580 tons of concentrate saved has an estimated value of \$97,425, making a total output of \$204,577. The total realizable value was \$202,531. Deducting \$81,866 for operating and \$24,206 for construction expenses, the estimated net profit was \$96,458. The yield per ton milled was \$2.49. The stock of broken ore decreased by 10,350 tons, and 1256 ft. of development was done on the 1450, 1600, and 1750-ft. levels.

### ARIZONA

#### COCHISE COUNTY

The tailing dam of the Detroit Copper Co. broke away on December 5, 1905, and several people were drowned and \$200,000 damage done at Clifton. A heavy rainstorm partly filled Chase creek before the dam gave way. The company refused to pay anything to the sufferers. A suit for \$200,000 damages was begun by 63 residents, and after some delay the jury brought in a verdict for the plaintiffs, which the judge set aside. An appeal was taken to the Supreme Court, which upheld the lower tribunal. In 1910, W. A. Pitt and 19 others again opened the case, and they have been informed that the case was taken up by the present Supreme Court, setting aside the former decision. They are suing for \$60,000 this time.

Construction has commenced on the 305-ft. stack for the Calumet & Arizona smelter. The foundation is of concrete and slag, and its diameter is 40 ft. Steel work for the sampler is complete, as well as for the roaster dust chamber. A good deal of work is under way and 270 men are employed.

#### GILA COUNTY

(Special Correspondence.)—The Inspiration Consolidated Copper Co. has appointed H. Kenyon Burch, who built the Miami concentrator, as its chief mechanical engineer. He will have charge of the design and erection of the 7500-ton mill and surface plant generally. The engineering work so far has been in charge of Repath & McGregor, of Douglas, who have done excellent work; but they have their hands full in the construction of the new smelters at Jerome, Douglas, and Clifton, hence the appointment of Mr. Burch. He is also designing the new plant for the Old Dominion mine at Globe, which will double the capacity of the 500-ton concentrator. Since the death of M. E. McCarthy, superintendent of the Live Oak mine, T. R. Drummond, formerly in charge of the Inspiration mine, has been appointed superintendent of both mines.

After reaching a depth of 1015 ft. in No. 3 churn-drill hole on the Barney group, adjoining the Live Oak mine, work has been stopped. No more holes will be drilled, and

the Lewisohns will relinquish their option on the property. Three holes, 1450, 600, and 1015 ft. deep, respectively, were drilled without cutting any ore, although sulphides of iron and copper were found in small quantities. No ore has been found in No. 2 drill-hole of the South Live Oak Development Co., which is over 655 ft. deep in granite. No. 5 drill-hole at the Southwestern Miami, which corresponds to No. 3 of the Barney group, has been stopped at a depth of 1015 ft., showing a little mineralized schist. This hole was put down at the junction of the Barney, Southwestern Miami, and Inspiration Consolidated properties, and the three companies shared the expense. Three more holes are being drilled, the deepest being 720 ft., and all are in schist. At the Miami mine two drills are working at the north-eastern part of the property, and a large tonnage of low-grade ore is proved. Diamond-drilling is still under way on the 570-ft. level.

Globe, July 25.

#### YAVAPAI COUNTY

The Buckeye Copper & Gold Co. has been formed to develop a group of 35 claims in the Turkey Creek district, which is said to contain copper and gold ore. One thousand tons of ore is being hauled from S. J. Tribolet's mine, near Goddard, to Phoenix. The Swansea smelter was blown in last Monday. About 200 men are employed at the mine and smelter.

### CALIFORNIA

#### AMADOR COUNTY

(Special Correspondence.)—Sinking has ended at the Hardenburg mine and a west cross-cut is being extended from the 1000-ft. level. This is planned to intersect the vein disclosed in the old workings. It is reported the shaft of the Bunker Hill is to be deepened and a steel head-frame built. The adit connecting with the shaft at the 250-ft. level has been reopened, permitting better ventilation and increasing the safety. In the mill 40 stamps are dropping steadily, treating ore yielding \$5 to \$5.50 per ton. Most of this is from the 1950 and 1750-ft. levels. July 15 the regular monthly dividend of 7½¢. was paid, a total disbursement of \$15,000. The Keystone company is sinking its 8 by 20-ft. shaft in hard greenstone. Last month 102 ft. was gained, considered excellent progress under prevailing conditions. A compressor, blower, and other machinery was recently installed. A steam-pump has been placed at the Defender, and unwatering of the property is well under way. The drift from the 1950-ft. level of the Lincoln has almost reached the Wildman mine, according to late reports. The drift is expected to intersect the big vein showing in the bottom of the Wildman shaft. The 10-stamp mill at the Newman mine has begun operation. A compressor and air-drills were recently installed. The mine lies near West Point. The Lockwood, in the same district, is being unwatered. The shaft has a depth of 325 ft. A new hoist was recently erected.

Jackson, July 28.

#### INYO COUNTY

During the month of June the Skidoo Mines Co. treated 1186 tons of ore for bullion valued at \$16,952. Development cost \$1399 and operating \$7819, leaving a net profit of \$7734. Ten days were lost during the period.

#### NEVADA COUNTY

An improved grinding pan has been invented by C. D. Tregoning, of Grass Valley, and a patent has been applied for. It is claimed that the new mill will grind one-third more than any mill of a similar type, taking into consideration wear and tear, and horse-power required for operation. One mill will be installed in a plant at Nevada City, and six have been ordered for Mexico. The mills will be manufactured at Grass Valley and Sacramento.

#### SIERRA COUNTY

A wagon load of ore valued at \$20,000 was delivered at the Lightner mill at Alleghany, and a jar of gold worth \$4000 was on exhibition at Downieville last week. This ore and gold was from the Ironsides mine, at the head of

Jim Crow canyon, nine miles from Forest. The claim was taken up about three years ago, and within the past few weeks about \$40,000 has been produced. Considerable interest has been shown in the district, and many miners are preparing to stake off surrounding country.

## COLORADO

### CLEAR CREEK COUNTY

(Special Correspondence.)—The Comet mine on Griffith mountain has been sold to Charles Rowlands, of Syracuse, New York. The property will be consolidated with the Ruler holdings and development started. Nels Williams is resident manager. Work has been resumed on the Ready Cash mine at Williams Fork. Shipments will be started early the coming fall. J. T. Johnson, owner of the Merrimac mine on Kelso mountain, has a force of men at work. The adit will be extended to intersect the Merrimac vein. L. Hoery, owner of the Phonolite property on Griffith mountain, has resumed operation. Driving is in progress on a body of lead-zinc ore that is 18 in. wide. A rich discovery has been made on the McClellan mine on Leavenworth mountain, a vein 14 in. wide, assaying 1500 oz. silver per ton, having been uncovered. The shoot is showing for a length of 60 ft., while there is 65 ft. of virgin ground overhead. A shipment of 75 tons will be sent out next week. Farragher & Co., leasing at the Gambetta mine on Republican mountain, started a shipment of two carloads of zinc ore this week. The product will be consigned to Denver. The Clinton property in the Daily district is again receiving attention. Drifting is in progress, while the adit will be continued. Bergen & Co., leasing at the Elephantine property on Covode mountain, have uncovered an 8-in. vein of gold-bearing ore that will yield \$18 per ton. The R. E. Deming lode on Democrat mountain is being prospected by J. W. Old. Small veins of ore are cut occasionally. Hummer & Herber, leasing at the Aetna vein, have opened a body of ore 2 ft. wide which returns \$25 per ton. Shipments are going to the Combination mill at Idaho Springs. Georgetown, July 27.

### GILPIN COUNTY

A number of Salt Lake men have formed a company to work the Buckley mine, on Gunnell hill. This mine is equipped with a boiler, hoist, compressor, and air drills, which have been overhauled. It is intended to sink the shaft from 630 to 830 ft., and then open out; also to prospect the upper levels of the lease where pay-ore is said to be showing. B. T. Lloyd is the manager. Operations will be resumed on the Gomer mine, in Russell district, this is an extension of the Rockford and Trail properties, which are producing ore. The Rockford is equipped with mining machinery. Ore is being broken on the 125 and 180-ft. levels of the Trail mine. The former level is in 35 ft. and shows 48 in., while the latter at 25 ft. shows 60 in. of ore. A shipment of smelting ore is being saved, and assays have returned 1.85 oz. gold, 22.2 oz. silver, and 14% copper, equal to \$72 per ton. The shaft is now 200 ft. deep. Lessees at the Grand Army mine are doing fairly well. From the 1000-ft. level  $10\frac{1}{2}$  tons of ore yielded 1.68 oz. gold and 4 oz. silver per ton. The vein is from 6 to 15 in. wide. The 700 and 800-ft. levels of the Alps mine, Quartz hill, are being opened up. The ore is from 12 to 18 in. wide, assaying 1.25 to 2.20 oz. per ton. The Pierce mine shows 48 in. of ore on the 500-ft. level.

### TELLER COUNTY (CRIPPLE CREEK)

Dividend No. 35, of 2c. per share, has been paid by the Mary McKinney company. There were produced during the first six months of the year 4711 tons of ore by the company, and 1895 tons by lessees, for yields of \$150,553 and \$30,085, respectively, making a total of \$181,046 after adding sundry revenue. Treatment and other expenses amounted to \$105,072, leaving the net income \$75,974. The cash balance June 30 was \$88,928. A heavy flow of water came in while sinking to the ninth level, and work will be delayed for about 30 days. The total pro-

duction to date is \$7,450,611. The Petrel claim on Squaw mountain has shipped five cars of ore, which will average about \$25 per ton. The vein being worked is from 18 to 36 in. wide. The Midget-Bonanza mine, on Gold hill, is producing nearly three carloads of ore per week. Mine gas has been troublesome at times. The erection of a mill to treat low-grade ore has been considered. The flow of water from the Roosevelt tunnel is 9640 gal. per minute, this being the average during the past six months. The water in the deep shafts of the district is receding about 4 in. per day. From the Strong shaft, below the old water-level, about two cars of high-grade ore is being produced per day. The El Paso company has almost completed sinking the Nicholls shaft to the 800-ft. level. A drift will be put in at this depth which is level with the 900-ft. of the old shaft, and the two will be connected. A new hoist is to be built at the Nicholls shaft. The mine is being examined by T. R. Countryman for certain stockholders who wish to find out the quantity of low-grade ore in sight, before a mill is erected for its treatment. At Stratton's Independence everything is in good order, and over 300 men are working on the property. A dewaterer has been erected at the mill, and the consumption has been much reduced. At Colorado City the United States Reduction & Refining Co. started treating

SHAFT OF EL PASO MINE.

the tailing from the Standard mill. Twenty-five men will be employed in the treatment of about 700 tons daily. There are 90,000 tons in the dump.

The operation of the Colburn mill, where the Moore-Clancy process is used, will be resumed in about 30 days. The rebuilding of the sampler has been delayed somewhat. Electric pumps for the Golden Cycle shaft have arrived and are to be put in at once. These pumps should reduce the present cost of lifting water by steam.

## MISSOURI

The Missouri-Kansas-Oklahoma district last week sent out ore valued at \$424,282, this total being the second largest return to date. There was 12,023,480 lb. of ore sold at high prices, 5,000,000 lb. coming from the Webb City-Carterville district. The J. R. Underwood mine at Granby shipped 460,790 lb. of calamine, and the yield from Galena and Duenweg was heavy.

## MONTANA

### FLATHEAD COUNTY

(Special Correspondence.)—The Kootenai Power Construction Co. has commenced the construction of the power plant at Kootenai falls, 12 miles west of Libby. It is proposed to develop 45,000 hp. at the falls, and engineers are now in the field estimating the amount of power that can be sold in the district to be covered, making contracts for power, and planning the distributing lines which will have to be constructed. The work to be done includes a dam 118 ft. high and the building of a railroad bridge across the Kootenai river. It is estimated that about 20 months will be required to complete the plant.

Libby, July 29.

**NEVADA****HUMBOLDT COUNTY**

The recent flood at Mazuma has been followed by the destruction by fire of the Mazuma Hills company's mill. There is just now no water-supply in the place. The origin of the fire is unknown.

**NYE COUNTY**

The new mill of the Tonopah Belmont Development Co. was started on July 25, and is working smoothly. Practically the same process is used as at the old mill at Millers, but there are many mechanical improvements. The plant consists of 60 stamps, 8 tube-mills, Dorr classifiers, 12 Deister tables, Pachuca agitators, and cyanide plant, and has a capacity of 500 tons daily. Pay-ore shows in the face of the drift on the Belmont vein at the 900-ft. level east; but the ore in the east drift on the vein in cross-cut 1001, on the next level, is low grade. Work has been resumed in the raise on the Shaft vein at the 1100-ft. level. On the 1300-ft. level the west drift on the Belmont vein found a good deal of water and was temporarily discontinued.

The west working on the 500-ft. level of the Manhattan Big Four company is 130 ft. long, and the northeast cross-cut has been advanced 50 ft. from the shaft. About 200,000 gal. of water is being handled daily. Ore assaying \$5.60 per ton was recently cut in the old Joker tunnel. Forty tons from the Lindsay Farrish lease 100-ft. level yielded \$14 per ton at the Priest mill.

At the Manhattan-Thanksgiving driving has been done on the levels above water-line. The shaft is down 425 ft. and a pump is working at this depth. A head-frame 36 ft. high has been erected at the Manhattan-Earl mine, while the electric hoist and air-compressor are on the ground.

**STOREY COUNTY**

The mines on the Comstock report the following work for the week ended July 27: Nine tons of ore, worth \$13.19 per ton, was saved in the stope under the sill-floor sets of the raise, 375 ft. from the entrance of the south-west drift on the 2400-ft. level of the Con. Virginia. The south drift at 2300 ft. is out 187 ft. in quartz and porphyry. Driving was continued on the 2000, 2200, and 2500-ft. levels of the Union Consolidated. The Mexican mill crushed 498 tons, assaying \$21.15 per ton. Four bars of bullion were sent to the Selby smelter. The Ophir shipped 339 tons to the Kinkead mill. The various cross-cuts are in porphyry and quartz. Water in the Yellow Jacket shaft is 41 ft. below the 1400-ft. station, and the shaft is being repaired. Other mines are busy, and a good deal of work was completed in the C. & C. and Ward shafts of the pumping association.

A suit of three years' standing, in which the defendants claimed that certain mineral land was open to location and disputed the right of the Union Pacific railroad to transfer it by sale, has been concluded in favor of the defendants. The mining property over which the case arose is in the Peavine district, 35 miles from Reno. This is an interpretation of the disputed law, with regard to mineral lands found on grants by the Government to railroad companies, and holds that title to such lands in instances of that kind, does not rest with the companies to whom it is transferred, irrespective of the transfer by deed of parts of the land by grant. The defendants had opened up ore on land which had been obtained by purchase by the plaintiffs from the Union Pacific. The grant as originally made to this company included every alternate section of land for a distance of 20 miles on each side of its line through Nevada. Most of this land has been transferred by sale or lease to private owners, but this decision will affect titles to mineral land only.

About 265,000 tons of tailing lying near the Cordelli ranch, on the Carson river, has been leased by D. Prentiss from W. Douglass. The tailing is the result of milling Comstock ores many years ago; and is estimated to contain \$7,000,000. A cyanide plant will soon be erected.

**NEW MEXICO****GRANT COUNTY**

Production from the Chino, for June, amounted to about 1,540,000 lb. of copper, as compared with 1,431,000 lb. in May and 1,415,000 in April. The steam-shovels in the first section of the mine are now in clean sulphide ore, which gives a good extraction in the mill.

**SANTA FE COUNTY**

On July 24 the smelter of the San Pedro Gold & Copper Co. was blown in. At present there are 200 men at the mine and smelter. The company has 3400 acres of property. The smelter, which has a capacity of 100 tons per day, is 21 miles from the Santa Fé railroad and 18 miles from Stanley. The copper matte will be refined at El Paso.

**OREGON****JOSEPHINE COUNTY**

Over 3000 acres of placer ground on Grave creek, fourteen miles from Grant's Pass, has been bought by the Oro Power & Light Co., of Oroville, California. Drilling is to be started at once, and it is said that about \$250,000 will be spent in prospecting and placing dredges on the property. The furnace at the Alameda mine was blown in last week, but several details are not yet completed, and these will take some 90 days. A fair quantity of smelting ore is ready for mining. Until the 200-ton concentrating plant has been erected it will be impossible to cheapen operations. The completion of the company's road from the mine to Leland should make a saving of about \$7 per ton on freight.

**LAKE COUNTY**

The Eureka Milling & Amalgamating Corporation was formed last week, with the object of erecting a custom plant for the High Grade district. The site for the mill has been chosen, and work will soon be started.

**TEXAS****BREWSTER COUNTY**

(Special Correspondence.)—A reawakening of active development in mining operations in the Quitman mountains district has begun with the reopening of the Bonanza mine, a zinc-lead-silver property, which has just been purchased by J. H. Johnson of Parral, Mexico, and associates. The holdings as obtained from the former owners, the Republic Mine & Milling Co., cover an entire section, one mile along the vein. Work has begun on the 300-ft. drift west from the shaft on the 150-ft. level and also on a drift east on the same level. The main shaft of the mine is about 300 ft. deep, with drifts on different levels. A 25-hp. gasoline hoist, superintendent's house, bunk and boarding houses for employees compose the improvements. Zinc and lead-silver ore which is easily extracted by hand is being taken out. Two cars of zinc have just been shipped from Lasca to Neodesha, Kansas. The lead-silver ore is being shipped to El Paso. The zinc ore is sphalerite or zincblende and assays from 40 to 57% zinc. The two carloads averaged 44% zinc. The lead ore is principally galena and averages 65% lead and 45 to 50 oz. silver per ton. The rich pay-streak runs from one foot to 18 in. wide in the upper levels, and as wide as 4 ft. in the lowest. About 30 men are working on the property.

The Bonanza mine was originally discovered in 1884 by T. R. Owen and George F. Miller, and was worked by them to a depth of 80 ft. Shipments were made to Kansas City smelters of ore averaging \$40 in lead and silver. These ores were lead carbonates with bunches of galena. In 1885 Bush Stevenson, of El Paso, purchased the property and worked it for several years, sinking a work-shaft 252 ft., hoisting a whim, and doing considerable driving and stoping. It is said that the first owners took out over \$1,000,000 of zinc and lead-zinc ore. Much rich ore was thrown over on the dump during this time, as there was no available market for the zinc ores. It was discovered that the mine was on railroad land, the Texas & Pacific

railroad securing title after suing Mr. Stevenson. After lying idle for a dozen years, it was purchased by a Weatherford, Texas, company, which erected a dry-concentrating and separating mill, with gasoline engine, crushers, and two tables, and began working on the dump ores in addition to taking ore from the mine. Operations soon ceased, however, owing to the unsatisfactory results obtained from the mill.

Alpine, July 29.

## UTAH

### SALT LAKE COUNTY

(Special Correspondence.)—The electrification of the Parvenue adit of the Utah Apex, a neighbor of the Utah Consolidated at Bingham, is practically completed, and the management hopes to increase the output. For some time 50 tons of concentrate and 100 to 125 tons of crude lead ore was shipped daily, and this has now been increased to about 200 tons per day.

Salt Lake City, July 29.

The Cardiff M. & M. Co. is shipping 40 tons per day assaying \$50 per ton. This ore comes from the south drift of the upper adit-level. A winze is now down 85 ft. from this level, and will be sunk 150 ft. farther to connect with the lower adit, which is now in 530 ft. The north drift from the upper adit is out 350 ft., with ore on each wall.

The mines and mining committee of the Commercial Club was last week addressed by E. L. Wolcott, assistant secretary of the American Mining Congress. It is asserted that certain legislation will make it a hard matter to secure patents on mining claims, and a revision of laws is necessary, because, through recent rulings and interpretations, they have become so involved and stringent as to virtually stop extension of mining in the West.

### SUMMIT COUNTY

(Special Correspondence.)—The Snake Creek adit, which is being driven by a company backed by the Daly-Judge and other Park City interests, is now in about 5000 ft., or about one-third the contemplated distance. A flow of 3600 gal. of water per minute has been developed, and this is being sold for irrigation. The face is in limestone, with indications of mineral.

Salt Lake City, July 29.

### TOOELE COUNTY

The quantity of lead ore being received at the Tooele plant of the International Smelting & Refining Co. is greater than the present capacity, so it is intended to erect a fourth furnace at once. Work on No. 3 smelter is being pushed, and by the end of the year the plant should have a capacity of 1200 tons per day. Five Dwight-Lloyd sintering machines are also being erected, making nine in all. The bag-house is being extended. Further enlargements are expected to meet increasing deliveries of lead ore.

## WISCONSIN

(Special Correspondence.)—Business is lively among the zinc mines in the southwestern part of the state. It is expected that the output this year will be worth even more than last. The Mineral Point Zinc Co. is increasing production at the Coker and Rajah. The Fox and the Kennedy are holding out well, and the mills 'pitch' in the Winnebago is proving exceptionally good. The south pitch in the same mine is yielding a lot of milling ore. The company recently bought the mining rights on the Ryan farm, near Galena, Illinois. Next to the Mineral Point company the Vinegar Hill Zinc Co., is the leading producer. W. N. Smith the active manager now has the Vinegar Hill, Trinity, Raleigh, Raisbeck, Wilkinson, and Ellsworth steadily producing, and is drilling on the Scrabble Creek and Hodge. The Wisconsin Zinc Co. is also expanding. The Interstate Power Co. is building rapidly from the south and the Mineral Point Power Co. from the north. There is a lively race to see which shall control the Mifflin fields. Highland is quiet, but producing steadily.

Pottsville, July 19.

## CANADA

### BRITISH COLUMBIA

On September 18 and 19 next, there will be a meeting of the Canadian Mining Institute at Victoria. It is hoped there will be a representative attendance, as the main object of the meeting is to afford Western members an opportunity to voice their views on certain business affairs of the Institute, including proposed amendments to the by-laws. Part of the time will be devoted to reading and discussing papers. Arrangements are also being made for a meeting at Lethbridge, in Alberta. E. Jacobs is secretary of the Western branch of the Institute.

### PORCUPINE DISTRICT

Four shafts at the Dome Lake mine are down 170, 160, 170, and 110 ft., respectively. Two veins are being developed, there being two shafts on each, about 900 ft. apart. These should soon be connected at the 100-ft. level. On the south end of the claim the lode is about 18 ft. wide for a good length, and shows pay-ore. Shafts C and D are on a rich vein, and 500 samples, taken over 800-ft. length, averaged \$23.80 per ton. Diamond-drilling has been continued to 500-ft. depth. A trial shipment at the Kingston School of Mines returned \$44 per ton. A plant consisting of 10 stamps and tube-mill is to be erected this year. The Porcupine East Lake company has decided to spend \$20,000 on sinking shafts and general development. The annual meeting of the Dome Extension company was recently held in Toronto. After paying sundry debts, the credit balance was \$15,338, while 199,993 shares remained as a reserve. Four shafts were sunk, totaling 639 ft., the total footage on all development being 2277 ft. On the 100-ft. level, from No. 4 shaft, a large lode was opened, and 30,000 tons, worth \$5 per ton, is in sight. Five diamond-drill holes were put down, with an aggregate depth of 3450 feet.

### ONTARIO

A slight mechanical change in the construction of the Deister slime-table has enabled F. Reid, mill superintendent at the Coniagas, to increase the efficiency of this table. An arrangement has been made with the manufacturers of the tables to have them introduced in other centres. It appears that tests have already been made in the Coeur d'Alene and Globe districts. The new table has been patented. The Toronto Metal Chemicals, Ltd., has purchased the old plant of the Electric Steel Co., and 10 acres of ground, at Welland. It is intended to erect a large plant in which Cobalt ores will be treated by a new process. During the week ended July 19, silver bullion weighing 153,888 oz. was shipped from Cobalt, the total for the year to this date being 2,680,100 ounces.

### YUKON

There has been a scarcity of water at Eureka creek, consequently only about half of the dumps have been washed. C. Hill and G. J. Stephens have been digging a ditch 5000 ft. long, so as to get water to finish sluicing. The general clean-up on the creek seems to have been satisfactory. One hundred and seventy-seven claims on Dominion creek and its tributaries have been transferred to the Dominion company; 29 on Quartz creek to the Calder company; 22 on upper Eldorado to the Deepvale company; 64 on Dago hill and 22 on Last Chance to the Dago Hill company; and 13 claims on benches on the right limit of the Dominion to the Big Creek company. This business was filed at the gold commissioner's office by A. N. C. Treadgold.

## MEXICO

### SONORA

The West Cananea mine is employing about 35 men, and is increasing its ore shipments. A new double-compartment shaft is being sunk at the Cananea-Boston property. The Mexican Metals company has 35 men working in the Alacran mine and the 10-stamp mill. The ore contains silver, zinc, lead, and copper.

## Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

**P** RINCIPAL air-compressor plants on the Panama canal are at Los Cascadas, Empire, Rio Grande, and Balboa. These furnish air to the Central and Pacific divisions and along the high line around Gold Hill on the relocation of the Panama railroad. For the year ended June 30, 1911, the total output of these plants aggregated 8,261,199,541 cu. ft. of free air, at a cost of 0.0324c. per 1000 cubic feet.

**L** AUNDERS made of wood are, on the whole, preferable to those of iron or steel, as the latter seem to be eaten away fairly quickly, especially if waters are slightly acid. Hot cyanide solutions also attack them. To prevent a wood launder from being cut out with coarse mill-pulp, tack old belting on its sides and bottom. This lasts a long time, and costs nothing save for the labor of fitting in a launder.

**B** ARYTES occurs in veins as a gangue of metallic ores, also in veins in sandstone and limestone or as a replacement of limestone. The mineral has a wide range in geologic time and an extensive distribution. In the United States the principal sources are, however, limited to two districts, the Missouri and the Appalachian. A single county in Missouri—Washington county—produced about 45% of the total output.

**A** RSENIC is used mainly in glass-making, in pigments, and insecticides. The use of paris green (aceto-arsenite of copper) in paint is somewhat limited on account of its poisonous quality. As an insecticide it is used largely by gardeners, orchardists, and farmers. If pure, it is comparatively harmless to plant life, owing to its insolubility, but the trioxide is often present in some quantity, and if paris green is then used it is fatal to plants, especially in dry climates, where it is not soon washed off by rains. Experiments conducted by a number of the state agricultural experiment stations have demonstrated the value of arsenic when combined with lime as an effective spray against insect pests.

**P** OWDER SMOKE can be quickly cleared from the face of an adit, where ventilation is secured by the use of a small blower and the usual galvanized-iron pipe, by reversing the direction of the blower. The smoke is thus sucked into the pipe and carried away without becoming mixed with the air of the adit or drift. A method commonly employed where machine drills are used is to turn on the compressed air just before firing the round of shots and allow it to escape continuously while the smoke is clearing away. The disadvantage of this is that the use of compressed air is an expensive means of securing ventilation, and since the smoke must be driven out through the full cross-section of the drift, a much longer time is required to clear away the smoke.

**A** NTIMONY is used as an adulterant in solder, but is considered an objectionable element, especially if the solder is to be used for sealing cans holding provisions. Antimony trioxide is used as a pigment in place of white lead and zinc oxide. It is also used for making the glass used to coat iron in enameled ware, as a reducing agent in chemical work, and as a detector of alkaloids and phenols. Antimony in various forms is used in medicine. The trichloride, also called antimony butter, is used in bronzing iron, especially gun barrels, as a mordant for patent leather, in coloring zinc black, as a mordant for silver, and in the manufacture of lakes, particularly from dye-woods. In some forms antimony is used in dyeing, and the trisulphide is used in fireworks for making 'Bengal fire.'

## Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

J. P. KEENE is back from Siberia.

M. K. RODGERS is in San Francisco.

JOHN B. FARISH is in San Francisco.

J. W. WHITEHURST is in San Francisco.

E. H. BENJAMIN has returned from Chicago.

J. H. MACKENZIE has returned from Alaska.

DONALD F. IRWIN is at Pasadena on a holiday.

G. W. SCHNEIDER was in San Francisco this week.

C. W. PURINGTON left London July 20 for Nome, Alaska.

WALTER LYMAN BROWN has left the Gold Coast for London.

HOWARD A. POILLON has returned to New York from Mammoth, Arizona.

H. D. SMITH has returned to San Francisco from the Santa Maria oilfields.

Information is wanted concerning JAMES C. MASON, last heard of at Los Angeles.

JOHN B. E. BELL is engineer for the Ft. Bidwell Con. Co., at High Grade, California.

MORRISON B. YUNG has returned from China and is at the Yale Club, New York City.

ERROL MACBOYLE, who has been in the hospital for appendicitis, is now at home and doing nicely.

DONALD F. FOSTER has gone to Prestea Block A by way of Secondi, Gold Coast Colony, West Africa.

HENRY H. ARMSTEAD has returned to Guanajuato, Mexico, from New York, and will be there about three months.

CHARLES POIRIER has resigned as manager and engineer at the Vipond mine to return to general consulting work.

FRED B. REECE, after spending two years near Quito, Ecuador, is now with the Dome Mines, Ltd., at Porcupine, Ontario.

J. A. CHESTNUT and W. W. WISHON have been visiting the properties of the Corem Mining Co., near Parker, Arizona.

W. S. TANGIER SMITH has removed from Reno, Nevada, to Berkeley, California, and will devote his time to general consulting work in geology.

C. M. EYE, who recently returned from a seven years residence in the Philippines, has accepted the management of the Concheño mines of the Corrigan-McKinney company, situated in the Rayon district of Chihuahua. Until resumption of regular mail service in Chihuahua, Mr. Eye's address will be the Concheño Mining Co., 420 Roberts-Banner building, El Paso, Texas.

## Obituary

W. H. SPENCER, a long time mining man, died at Nyack, New York, July 10, and was buried at Haileybury, Ontario.

M. E. MCCARTHY died of heart failure on July 16 while returning from the Inspiration mine to Globe. He was manager of the Hovland and Smith properties for the past six years, and had developed the Live Oak mine of the Inspiration Consolidated from a prospect. He was one of the best liked mine managers in the district.

H. O. PELLHAM, a native of New York state, engaged in mining in Mexico for the past fifteen years, died June 3 at Calabacillas, Chihuahua, of congestion of the lungs. He had charge of several wells at the Lluvia de Oro, Topia, Calabacillas, and other places, was liked and respected by the Mexicans and all Americans.

## LOCAL METAL PRICES

San Francisco August 1.

San Francisco is not a primary market for the common metals except quicksilver. The prices quoted below therefore represent sales of small lots and are not such as an ore-producer could expect to realize. Ore contracts usually call for settlements on the basis of Eastern prices, less freight and treatment charges. The prices quoted are in cents per pound, except in the case of quicksilver, which is quoted in dollars per flask of 75 pounds.

Antimony.....11-11½c	Quicksilver (flask).....43
Electrolytic Copper.....17½-18c	Tin.....50-51½c
Pig Lead.....5.00-5.95c	Spelter.....8-8½c
Zinc dust, 1400 lb. casks, per 100 lb., small lots \$9.50-9.75; large \$7.50-8.50	

## METAL PRICES

(By wire from New York.)

NEW YORK, August 1.—Copper prices are now stronger and a better demand for the metal in this country is clearly apparent. Lead is easier with no change in immediate prospect. Spelter remains firm and prices are steady.

Average daily prices for the past week, in cents per pound, based on wholesale transactions, standard brands, are given below.

Date.	Electrolytic Copper.	Lead.	Spelter.	Silver, per oz.
July 25.....	17.48	4.73	7.13	60½
" 26.....	17.48	4.73	7.08	60½
" 27.....	17.48	4.73	7.08	60½
" 28.....	Sunday.	No market.		
" 29.....	17.45	4.73	7.08	60½
" 30.....	17.45	4.73	7.05	60½
" 31.....	17.45	4.73	7.05	60½

## SILVER

Below is given the average New York quotation, in cents per ounce, of fine silver for the months indicated:

	1911.	1912.	1911.	1912.
Jan. ....	53.81	56.25	July .....	52.57
Feb. ....	52.23	59.06	Aug. ....	52.17
Mch. ....	52.76	58.37	Sept. ....	52.43
Apr. ....	52.32	59.20	Oct. ....	53.37
May ....	53.31	60.88	Nov. ....	55.77
June ....	53.04	61.29	Dec. ....	54.85

## COPPER

Daily quotations on copper as published in this column represent average wholesale transactions on the New York market and refer to electrolytic copper. Lake copper commands normally from 1-5 to 1-4c. per lb. more. Below are average monthly quotations in cents per pound:

	1911.	1912.	1911.	1912.
Jan. ....	12.29	14.09	July .....	12.47
Feb. ....	12.26	14.08	Aug. ....	12.41
Mch. ....	12.14	14.68	Sept. ....	12.20
Apr. ....	12.02	15.74	Oct. ....	12.19
May ....	11.99	16.03	Nov. ....	12.61
June ....	12.39	17.23	Dec. ....	13.55

## COPPER SURPLUS

Figures showing the visible supply of copper at the beginning of each month are now widely available. Below are given the amounts, in pounds, known to be available at the first of each of certain months.

	U. S.	European.
January 1910.....	141,766,111	244,961,280
January 1911.....	122,030,195	230,264,280
November ".....	134,997,642	176,816,640
December ".....	111,785,188	164,151,680
January 1912.....	89,454,695	178,329,920
February ".....	66,280,643	153,820,800
March ".....	62,939,988	141,125,680
April ".....	62,367,557	137,806,000
May ".....	65,295,368	134,176,000
June ".....	49,615,643	117,801,600
July ".....	44,335,004	107,817,920

## UNITED STATES PRODUCTION AND CONSUMPTION

(Compiled from reports of the Copper Producers' Association)

	Production.	Domestic deliveries.	Exports.
June 1911 .....	124,554,312	61,655,561	71,460,519
July .....	112,167,934	56,982,582	74,880,658
August .....	125,493,667	59,935,364	69,885,660
September .....	115,588,950	57,311,584	50,824,011
October .....	118,255,442	64,068,656	60,084,349
November .....	111,876,601	68,039,776	67,049,279
December .....	122,896,697	65,988,474	79,238,716

Total for 1911.....	1,431,938,338	709,611,945	754,932,733
January 1912 .....	119,337,753	62,343,901	80,167,904
February .....	116,035,809	56,228,368	63,148,096
March .....	125,694,601	67,847,556	58,779,566
April .....	125,694,001	69,513,846	53,252,326
May .....	126,737,836	72,702,237	69,485,945
June .....	122,315,240	66,146,229	61,449,650

## LEAD

Lead is quoted ordinarily in cents per pound or dollars per hundred pounds delivered at St. Louis or New York. The difference is normally 15c. per hundred pounds, and any larger or smaller difference is promptly met by sales. The daily price in New York is published each week in this column. Below are the average quotations by months:

	1911.	1912.		1911.	1912.
Jan. ....	4.48	4.43	July .....	4.50	4.71
Feb. ....	4.44	4.03	Aug. ....	4.50	....
Mch. ....	4.39	4.07	Sept. ....	4.48	....
Apr. ....	4.41	4.20	Oct. ....	4.27	....
May ....	4.37	4.20	Nov. ....	4.30	....
June ....	4.34	4.40	Dec. ....	4.45	....

## ZINC

Zinc is quoted as spelter, standard Western brands, and based upon St. Louis or New York delivery. While New York quotations, as a matter of convenience, are commonly used, relatively little spelter actually goes to or comes from New York. The bulk is shipped direct from the plants in the Mississippi Valley to manufacturers, due allowance being made for freight. New York daily quotations are published in this column each week. Below are given averages by months:

	1911.	1912.		1911.	1912.
Jan. ....	5.45	6.42	July .....	5.70	7.12
Feb. ....	5.52	6.50	Aug. ....	5.95	....
Mch. ....	5.56	6.57	Sept. ....	5.86	....
Apr. ....	5.40	6.63	Oct. ....	6.10	....
May ....	5.35	6.68	Nov. ....	6.38	....
June ....	5.50	6.88	Dec. ....	6.30	....

Zinc-dust is quoted separately, the price being based upon the cost of spelter in Illinois and the cost of preparation. About half the zinc-dust used in the United States is imported through San Francisco. Delivery prices are determined largely by quantities and contracts.

## QUICKSILVER

The primary market for quicksilver is San Francisco, California, being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average monthly quotations, in dollars, per flask of 75 lb., are given below:

	1911.	1912.		1911.	1912.
Jan. ....	44.60	43.75	July .....	48.00	43.00
Feb. ....	48.40	46.00	Aug. ....	50.00	....
Mch. ....	52.50	46.00	Sept. ....	47.50	....
Apr. ....	50.90	42.25	Oct. ....	46.12	....
May ....	46.50	41.75	Nov. ....	45.50	....
June ....	46.50	41.30	Dec. ....	44.50	....

## TIN

New York prices control in the American market for tin, since the metal is almost entirely imported. San Francisco quotations, averaging about 5c. per lb. higher than New York, are quoted weekly in this column. Below are given average monthly New York quotations in cents per pound:

	1911.	1912.		1911.	1912.
Jan. ....	41.25	42.53	July .....	42.40	44.25
Feb. ....	41.61	42.96	Aug. ....	43.32	....
Mch. ....	40.16	42.58	Sept. ....	39.75	....
Apr. ....	42.18	43.92	Oct. ....	41.18	....
May ....	43.11	46.05	Nov. ....	43.12	....
June ....	44.61	45.76	Dec. ....	44.65	....

## Current Prices For Chemicals

(Corrected monthly by Braun-Knecht-Helmann Co.)

Prices quoted are for ordinary quantities in packages as specified. For round lots lower prices may be expected, while in smaller quantities advanced prices are ordinarily charged. Prices named are subject to fluctuation. Other conditions govern Mexican and foreign business.

	Min.	Max.
Acid, sulphuric, com'l, 66°, drums, 100 lb.....	\$0.75	\$1.00
Acid, sulphuric, com'l, 66°, carboy, 100 lb.....	1.00	1.50

## Current Prices for Ores and Minerals

(Corrected monthly by Atkins, Kroll & Co.)

The prices are approximate, subject to fluctuation, and to variation according to quantity, quality, and delivery required. They are quoted, except as noted, f.o.b. San Francisco. Buying prices marked \*.

	Min.	Max.
Antimony ore, 50%, 100 ton .....	\$20.00	\$22.50
Arsenic, white, refined, 100 lb.....	0.04	0.04½
Arsenic, red, refined, 100 lb.....	0.08	0.09
Asbestos, according to length and quality of fibre, 100 ton .....	100.00	350.00
Asbestos, lower grades, 100 ton .....	5.00	50.00
Asphaltum, refined, 100 ton .....	10.00	20.00
Barium carbonate, precipitated, 100 ton .....	42.50	45.00
Barium chloride, commercial, 100 ton .....	42.50	45.00
Barium sulphate (barytes), prepared, 100 ton .....	20.00	30.00
Bismuth ore, 10% upward, 100 ton .....	*75.00	upward
Chrome ore, according to quality, 100 ton .....	10.00	12.50
China clay, English, levigated, 100 ton .....	15.00	18.00
Cobalt metal, refined, f. o. b. London, 100 lb.....	2.50	....
Coke, foundry, 2240 lb .....	13.50	15.00
Diamonds:		
Borts, according to size and quality, 100 carat .....	2.00	15.00
Carbons, according to size and quality, 100 carat .....	50.00	90.00
Feldspar, 100 ton .....	5.00	25.00
Firebrick:		
Bauxite, 100 M .....	175.00	....
Magnesite, 100 M .....	190.00	275.00
Silica, 100 M .....	42.50	47.50
Flint pebbles for tube-mills, 2240 lb .....	19.50	22.50
Fluorspar, 100 ton .....	15.00	15.00
Fullers earth, according to quality, 100 ton .....	20.00	30.00
Gilsonite, 100 ton .....	35.00	40.00
Graphite:		
Amorphous, 100 lb.....	0.01½	0.02½
Crystalline, 100 lb.....	0.04	0.13
Gypsum, 100 ton .....	7.50	10.00
Infusorial earth, 100 ton .....	10.00	15.00
Magnesite, crude, 100 ton .....	5.00	7.50
Magnesite, dead calcined, 100 ton .....	23.50	27.50
Magnesite, brick (see firebrick) .....	....	....
Manganese ore, oxide, crude, 100 ton .....	10.00	25.00
Manganese, prepared, according to quality, 100 ton .....	30.00	70.00
Mica, according to size and quality, 100 lb.....	0.05	0.30
Molybdenite, 95% MoS₂, 100 ton .....	400.00	500.00
Monazite sand (5% thorium), 100 ton .....	150.00	200.00
Nickel metal, refined, 100 lb.....	0.45	0.60
Ochre, extra strength, levigated, 100 lb.....	2.25	3.25
Platinum, native, crude, 100 oz .....	40.00	45.00
Silica lining for tube-mills 2240 lb.....	32.50	35.00
Sulphur, crude, 100 ton .....	15.00	25.00
Sulphur, powdered, 100 ton .....	40.00	45.00
Talc, prepared, according to quality, 100 ton .....	20.00	50.00
Tin ore, 60%, 100 ton .....	450.00	475.00
Tungsten ore, 65% .....	390.00	455.00
Vanadium ore, 15%, 100 ton .....	150.00	180.00
Wolframite (see tungsten ore) .....	....	....
Zinc ore, 50% up, 100 ton .....	*15.00	20.00

## EDITORIAL

FIRE is one of the ever-present dangers in mining that is all too little considered. Because of the confined circulation a relatively small fire has repeatedly caused large loss of life. Since mine structures are nearly always temporary and are designed for short life only, fire-proof construction is seldom practicable. Added to this is the fact that at many mines water is extremely scarce. All in all, the danger from fire deserves more careful consideration, and the mine manager who does not have well matured plans for fighting fire, as well as efficient apparatus, is criminally careless. We print this week the outline of a proposed comprehensive study of fire risk around mines, and commend it heartily to our readers. If each will send to Mr. R. Y. Williams, secretary of the committee, notes on his experience and suggestions that have grown out of it, an excellent and helpful report should result.

NEVADA was admitted as a state during the Civil War, and as Nevada's vote gave Lincoln a bare majority in Congress in support of his war measures, it became the savior of the nation; a fact that citizens of the state like to remember. The souvenir edition of the *Nevada State Journal* recalls this bit of history and contains much of interest in regard to the resources and industries of the state. The mines of the Comstock Lode had much to do with the early building of the West, by contributing wealth, and by acting as a magnet to attract immigration. The practice of mining as developed in the Comstock mines was carried through all the districts of the West and many successful operators received their early training in the levels and stopes of these famous mines. That mining is still the leading industry of Nevada is evidenced by the long list of producing companies operating within its boundaries. Ely, Tonopah, Goldfield, and Virginia City are all names to conjure with, and any state may well be proud to claim these districts. Reports of the county auditors show the gross value of the yearly production of the mines in the state to be \$32,000,000.

ANNOUNCEMENT that Hayden, Stone & Co. have taken an interest in the Alaska Gastineau properties will be read with great interest. The principal mine involved is the Alaska Perseverance, though coupled with it are properties on Sheep creek to the south. The group constitutes the southern part of the great lode that runs through Silver Bow basin back of Juneau. To the immediate north is the Alaska Juneau, and beyond that the Ebbners. The large size of the orebodies has been established. Up to the present none of the properties on this lode have been adequately financed, and with ore worth but \$1.50 to \$2.50 per ton, large scale operations are imperative. It is proposed to tap the Alaska Gastineau orebodies at depth by means of an adit and to erect a large mill on the channel below Juneau, following essentially the same lines as already adopted by the Alaska Juneau and discussed last week. There is every prospect of success, since failure in the past was due rather to bad financing than poor mining, Mr. John R. Mitchell, the man on the ground, having made the best of a poor situation. With

the death of W. J. Sutherland the properties came under the control of Messrs B. L. Thane and W. P. Hammon, and now that adequate funds are to be provided, another large low-grade gold mine in the Juneau district would seem to be assured.

COLORADO is feeling much encouraged over present prospects. Crops are in good condition and promise an unusually large return. As agriculture is now so large a factor in the business of the state, this means much. While final figures of mineral production in 1911, compiled by Mr. C. W. Henderson for the United States Geological Survey and printed on another page, show a slight decrease as compared with 1910, they do not tell the whole story. It is well known that development of tungsten and other rare-mineral mines has gone on *pari passu* with the fall in output of gold and silver. Zinc production continues to increase, and the copper output, while always small in Colorado, is growing. The rise in the price of silver has helped, and the deeper levels at Cripple Creek are doing their part in augmenting gold production. More important, however, is the progress being made in treatment of low-grade ore. The Independence, Portland, and Ajax mills at Cripple Creek have each shown that ore long thrown over the dump can be made to yield a profit. With perfection of metallurgical processes it should be possible to treat ore in Colorado of as low value as in South Dakota or Alaska. Water, fuel, and intelligent labor are available. Living conditions are excellent, and growth of other industries, while it detracts attention from mining, should in the end bring down costs. No one who knows Colorado doubts that her mountains contain large stores of unbound metal, and no one who knows her people doubts that there will be steady progress in methods. The last few years have been hard, but prospects are now excellent.

ALASKAN conditions were excellently reviewed in a recent address by the energetic and well informed Governor of that territory, Mr. Walter E. Clark. We elsewhere print a part of what he said. It will come as a shock to many, even now, to know to what extent the common functions of government have been neglected, and anyone familiar with the difficulty in obtaining legislation at Washington will hope that at least some measure of self-government will be granted to Alaskans. In so large a territory with so scattered a population any government will be expensive, so that the simple form now proposed at Washington is better than the more complete territorial governments that served in what are now states. Help from the national treasury will be needed in Alaska for many years, but the period of probation will be much shorter if a vigorous and statesmanlike program of railroad building and development be resolutely taken up. We may not all agree as to theories of government ownership, but we should be willing to face facts, and, as we see it, the only practicable means of opening Alaska now is through government building of trunk lines and leasing of the coal lands. Public sentiment will not sanction a return to old conditions of staking as regards the land, or to bond guarantees or land grants in aid of roads. To stubbornly insist on such a return is as fatuous as to refuse to vote money for a railroad line because of a prejudice against government ownership. Trunk line railroads in Alaska, privately owned, do not pay and will not pay except on the basis of exploitation rather than development of the adjacent territory. The America people have had a bitter taste of that in many Western communities and are not likely to repeat the experience. To make new mistakes may be condoned, but to make the same mistakes repeatedly is unpardonable.

## Politics and Business

Politics is booming, and so is business. This is an unusual coincidence. Usually activity in politics destroys industry. This year, however, as political wheels revolve, they but keep time to the wheels of industry; and political wires are not more strained than are the more prosaic ones that carry ordinary messages of bargain and sale. The condition demands explanation. Ordinarily the year of a presidential election in the United States is a hard one for business men. No one is ever entirely certain of the result until the votes are counted, and even those who feel sure as to the outcome of the election, are not sure how the public will react. Notable booms and equally notable depressions have followed elections. Four years ago there was no real doubt as to the approaching election of Mr. W. H. Taft. There was, however, great doubt as to the result. He was squarely and fairly on record as favoring a tariff revision, and in popular belief the revision was to be downward. Many business men remained skeptical, and as it proved wisely so, as to any substantial decrease of duties. No one knew the terms upon which business was to be transacted through the succeeding four years, and those who could do so shortened sail. There was in addition a deep resentment among many leaders of industry, against Mr. Roosevelt for his radical and often erratic program. It was felt that a determined effort should be made to capture the new administration and check tendencies held to be dangerous. The effort was made, and was successful; the new administration being promptly heralded as 'safe and sane.' It was to be 'progressive,' but not too aggressive.

The result was hardly what was hoped or anticipated. The general public had looked upon Mr. Taft as having been elected to continue the work begun by Mr. Roosevelt, and whatever may be individual opinion as to his fidelity to the trust, there can be no doubt that he signally failed to satisfy the people. The past four years, as a result, have been spent in constant political turmoil. The conservative element won in framing the Payne-Aldrich tariff act, but thereby precipitated a longer and more bitter fight. With ever present prospect of still other changes, business men kept close to the financial shore. Mr. Taft and the Attorney General, Mr. G. W. Wickersham, instituted and fought through the courts a series of suits dissolving the great corporations popularly known as 'trusts.' By their insistence on the letter of the Sherman act, they scared and worried business men, though in the end accomplishing nothing that appealed to the public as substantial. Dissolving the trusts and thereby restoring competition has become a joke. As one result of the past four years the Republican party has gone to pieces. The leaders have kept the machinery but lost the voters, and at present the party is like a Central American army, composed mainly of generals. Whether it can be reconstructed or not is not now apparent. Mr. Roosevelt was undoubtedly the choice of the majority of Republican voters for standard bearer this year. At Chicago he was defeated in convention by sharp practice; by the same political tricks and devices that have been repeatedly used in the past. Hard names mend no broken bones, and it does little good to shout 'thief.' We have an impression that iteration and reiteration of the term has hurt the progressives rather than helped them. Mr. Roosevelt's most serious limitation, politically, has long been his inability to see that others were traveling in the same direction, if they chanced to be on another road. Many of the men who defeated him at Chicago were quite as sincere in considering it their duty to crush what they believed to be a dangerous movement led by a rash man, as

was he in fighting to secure from the convention the endorsement that was already his by right of expression of the voters at the primaries. The result was inevitable. Any compromise was not only impossible, but would have merely aggravated the situation. The conservatives had their way in the nomination of Mr. Taft, and as a necessary corollary Mr. Woodrow Wilson was nominated by the radical Democrats at Baltimore. Both are men of high character and ability, and with the issue sharply defined it would have seemed that there was no room for a third party candidate, especially in view of the long series of unsuccessful efforts to build up a third party.

This situation has not, seemingly, discouraged Mr. Roosevelt and the men associated with him, and the Progressive party has now been formally launched. Essentially it consists of the more radical part of the old Republican party. Whether it ever comes to include more will be determined by the course of events in the next four years rather than in the next three months. It is hardly likely that the Progressives expect to elect Mr. Roosevelt, though they will undoubtedly carry some states and make a showing in the electoral college. From a political point of view, their play is to thoroughly discredit their late opponents in the Republican party by making Mr. Taft run third in the race. It will be well worth their while to do so, even in the face of certain defeat at the hands of the Democrats, and the attempt to build up a national party free from sectionalism is one in which there is much to commend. As to the immediate result there is every reason to anticipate Mr. Wilson's election. He will lose few votes to the Progressives, since he is as much a radical candidate as is Mr. Roosevelt, and with the loaves and fishes so near at hand, the experienced politicians in the Democratic party are not apt to desert in order to join the Republicans in almost certain defeat. The trouble will come after the election. Mr. Wilson's nomination was notoriously forced upon the managers of his party, and they, as astute politicians, will make the same effort after his election, if he be elected, to control the administration, as was made by 'the organization' in the Republican party after Mr. Taft came to the chair. Whether they succeed or fail, the result seems equally certain to split the Democratic party as it has the Republican. Four years from now the Progressives, as an effective fighting force, will either form the nucleus around which all the radicals may centre, or, in case Mr. Wilson retains control of his party and succeeds in losing Tammany and other undesirable elements, will fuse with the Democrats. In either event it is unlikely that there will be any sharp change in policy or any aggressive program for four years. In other words, business must face at least four more years of substantially the same political conditions as in the four that have just closed. Whoever is elected president, and whatever party may control Congress, there will be tariff revision; but it seems certain that the lowering of the rates, to which majority sentiment has now come to be favorable, will be slow. As to trust legislation there is less certainty. Mr. Taft may 'run amuck' with prosecutions, but little practical harm to business seems to result. Mr. Roosevelt would favor Federal supervision, but has no illusions as to the ability or necessity of the government to dissolve trusts. Mr. Wilson, while protesting against exploitation by 'big business,' will necessarily go slow, and the long record of the Democratic party in favor of state's rights assures that any Federal regulation drafted by it will be slight. Some such bill as that introduced by Mr. John Sharp Williams, and an excellent bill it is, would stand the best chance of enactment by Democrats.

In the meantime, business men are tired of politics. Initiative, referendum, and recall may be all that their advo-

cates proclaim—but a man must make a living. A business man cannot indefinitely stay out of the market either for spite or through fear of what may happen. Nothing very radical has yet come about, and the bark of the radical has been worse than his bite. The country has had a needed rest from speculation, prices are good, crops are good, and a little good nature is all that is needed to set off a veritable boom.

### Land Fund of the Institute

An appeal is being made by Dr. James Douglas, as chairman of the committee of the American Institute of Mining Engineers, for funds with which to discharge the debt incurred when the Institute joined the American Society of Mechanical Engineers and the American Institute of Electrical Engineers, in accepting Mr. Carnegie's gift of an engineering building in New York. The whole matter has again come to the front in connection with the report of the Committee of Five, which we have already discussed. Briefly, Dr. Douglas states that toward the original debt of \$180,000, a total of \$112,000 has been subscribed and \$106,000 paid. To clear the remaining debt, \$21.14 is required per paying member. If, however, the amount be paid in five annual installments the contribution of each should be \$4.71 per year. Since, however, the mortgage is not due till 1925, an even smaller amount per year would permit the annual payments to be met. For our part, we believe that if the economies in administration already proposed by the committee do not permit the annual payments to be made, such a small temporary increase in dues should be voted. Any attempt to make the increase large enough to pay the whole sum in five years or less, would doubtless lead to many resignations. We have no fear that the money will not be raised, and in due time, but we hope it will come in the form of numerous small subscriptions. There is one phase, however, of Dr. Douglas' appeal that invites comment. The proposal to accept the building and buy the ground was agreed to by an affirmative vote equal to 99.25 per cent of the membership. On the other hand, the money so far subscribed has come from 91 members. Five members have given over half the total, and \$93,000 has come from subscriptions of over \$1000 each. Clearly, the wealthy members of the Institute have, in the main, done their part. Another surprising fact is that \$95,000 of the total has come from members residing in New York and Pennsylvania. Western members, while voting enthusiastically for the project, have not generally subscribed to the fund. Colorado is the only state west of the Mississippi from which as much has been subscribed as has been given by members resident in England, Australia, and Mexico. Utah, Nevada, Arizona, South Dakota, New Mexico, Oregon, and Washington have given nothing, unless they have a part in the \$64.67 credited to "scattering U. S." California has a proud total of \$450, while Montana has contributed \$100. We think that when Western members see these figures and realize the situation they will wish to wipe out the inequality in the showing, regardless of the final action that the Institute may take. Any scheme for temporary raising of dues and any funds derived from economies in operation, will fall alike on those who have given and those who have not, but we do not believe that Western members want the record to stand as it is, and we urge all who can do so to send checks to Dr. Douglas at once. The Institute is going through a period of reorganization. It is certain to be a much more vital organization in the future, and the keynote of the new régime is to be active participation by all the members. This is an excellent time for a little advance participation.

## Gold Placers of Arizona—Dry Washings of Value

By T. LANE CARTER

Arizona is known as one of the greatest copper districts of the world. It now leads in the United States, having left Michigan and Montana far behind. It will be a surprise to some that this great copper state is also a large producer of gold, amounting in recent years to from \$2,500,000 to \$4,300,000. A large portion of the gold of Arizona comes as a by-product from copper smelting. There are some free-milling gold mines of considerable value, and with the recent improvements in cyaniding, it is possible now to treat auriferous ores that until lately were useless.

The amount of gold taken from placers in Arizona is comparatively small. Scattered over the state are thousands of acres of gold-bearing material which could produce millions if Arizona were well watered instead of semi-arid. The scarcity of water has been the main draw-

lone miners in Arizona trying to make a living by 'dry washing' the placers. Many of these men are Mexicans, and they stick at the work far better than the white men because they are more easily satisfied and generally have a flock of children and relatives to help in the work. A photograph accompanying this paper gives a view of a small hand machine used by the Mexicans in Arizona. There are few finer mining climates in the world than that of Arizona. In placer mining, the climate is of large importance, as all know who have tried to carry on placer work in northern Alaska or Siberia. There will never be trouble in the Hassayampa district from freezing water or burst pipes.

Until the engineer becomes acquainted with the peculiarities of the placer ground along the Hassayampa river he is liable to be much mistaken in the value of the ground.

FIG. 1. CROSS-SECTION OF THE PLACERS.

back to the development of this industry in Arizona. Many men have been at work on the problem of getting the gold out of these placers without the use of water. In some parts of the state the problem is complicated, as it is in Sonora, Mexico, by the fact that the gold-bearing material is held together by a calcareous cement, necessitating the disintegration of the gravel before the gold can be taken out.

Machines such as the Quener disintegrator have been designed, to break up the gravel before it is treated by a 'dry-wash' process. It is only recently that the idea of using these refined methods of extracting the gold from the Arizona placers by 'dry washing' has been taken up. For many years individual miners, both the peons of Mexico and the white men, have been getting out gold from the placers of Arizona without the use of water. The methods used were most crude, requiring material of very high grade to make it worth while. I have inspected stretches of gold-bearing gravel in Arizona and noticed here and there small excavations showing where the dry-placer men had been 'high-grading' the country. On occasions in the past there has been a regular rush to certain districts of Arizona where the ground was reported to be rich, and individual miners could get out a high daily wage by simply 'rocking' the material.

On the Hassayampa river there have been several such local excitements in the past. At one time there was a camp of about 100 men on the banks of the river about 60 miles north of Phoenix. These men were busy picking out the rich spots in the placer ground and working them in a crude way by 'dry washing.' While none made fortunes, a great number of gold nuggets were found, and the majority of the men did very well as long as rich ground was found. To work the material successfully it had to be perfectly dry. A slight shower would so dampen the earth that the men could do little or nothing for many days. Their working time was, therefore, rather uncertain and limited. Now and then one comes across a couple of

As a general rule the country is full of small, narrow passages or 'washes', down which the water rushes to the river after a torrential rain. This peculiarity is illustrated graphically in Fig. 1. To the engineer going up the 'washes' A, B, and C, and examining the ground, he will find, perhaps at 1, 2, and 3, very rich placer ground if he puts down pits to bedrock. On testing the ground up these 'washes' he will find that the depth of the material rapidly pinches out on either side of the 'wash' until it gets to the top, where, as at D, E, and F, there is no pay-dirt at all. As these 'washes' are far apart, it will be seen that there is a comparatively small tonnage at any one place. For this reason a number of capable engineers have condemned the region around the Hassayampa river in the past, saying that while there are rich spots of high-grade placer ground, the tonnage at any one place is so small that it will not pay to work it by modern methods. While this in general is true, there are exceptions to the rule, as at a property which I recently investigated on the Hassayampa river.

Instead of the narrow 'washes' as illustrated in Fig. 1, I found there a stretch of placer ground in 'washes' averaging 1200 ft. wide, and about  $2\frac{1}{2}$  miles long. The average depth to bedrock of this material is 10 ft., and the average value per cubic yard, as determined by hundreds of pits sunk to bedrock and thousands of pannings of the material, is 40 cents. As these 'washes' contain about four to five million cubic yards of placer ground, it is obvious that this property is in an entirely different class from many of the other Arizona placer properties which have been examined and condemned.

The property is about 45 miles northwest of Phoenix, Arizona, and five miles from the station of Morristown on the Santa Fé railroad. The mine is well situated at an elevation of about 2000 ft., and, as is usual in Arizona, the health conditions are ideal in spite of the excessively high temperature in the summer. The property consists of nearly 4000 acres of placer ground. As the roads lead-

ing from the station to the mine are good, there is no difficulty in transporting freight from the railroad. The water runs away so rapidly after the heavy rains that the roads are never muddy for more than a few hours.

This placer ground is situated in a rolling country, the highest point in the immediate neighborhood being San Domingo mountain or hill, about a mile or so from the mine. The surface is scarred by frequent watercourses, down which the water runs in torrents after a heavy rain to the Hassayampa. The watercourses are so steep that this water stays only a short time after a heavy storm. The property, which is called the Lotowana mine, was found a few years ago by John Sanger, who noticed a few Mexicans working here and there, 'dry washing' the rich spots of the ground, but only obtaining from one-quarter to one-third of the gold. To his experienced eye it was obvious that here was the making of a big mine, if modern methods were introduced. He wisely gave up all attempts to mine the gold by the crude method generally adopted, and devoted all his attention to staking out and buying claims, feeling that if he could show up

deposited in these 'washes' very gradually, and there has not been a concentration of the gold on the bedrock such as is generally found in placers that have been formed by swift-flowing rivers. That the gold has not traveled far is proved by the fact that it is very angular; entirely different from the round water-worn nuggets seen in the placers of California and elsewhere. The majority of engineers, on examining samples of gold from the Lotowana mine, would declare it came from a vein rather than placer ground.

As is usual with gold from placer mines, the fineness of the metal on this property is high, being 900 and over. There is practically no 'float' gold, and the percentage of recovery in washing operations will therefore be high. Most of the gold will be caught in the riffles near the top of the sluice-boxes, but as a precaution mercury should be used at the lower end of the boxes. The question of the physical character of the gold is, of course, a most important one in placer mining. Many a property which has shown gold in profitable quantities has proved a failure in working conditions because the gold was in 'float'

HAND MACHINE USED IN ARIZONA DRY PLACERS.

DRY PLACERS ALONG THE HASSAYAMPA RIVER, ARIZONA.

a large profitable tonnage it would be practical to get water to the ground and treat this gravel.

The geology of the district is most interesting. There has been considerable denudation. Many of the rocks in the mountain and hill to the rear of the placer carry gold in minute quantities. The placer ground which it is proposed to work on this property has been formed in the accumulation of débris coming down from the low mountains, composed of pre-Cambrian schists, gneisses, and granites. The limestone, which in some places cements the gravel, is of Paleozoic age. The mineralizing agents are the intrusive rocks, granites, and porphyries. Micaceous schists which outcrop in the northern part of the property dip to the south. In the schists near the property are numerous quartz veins, most of them barren, but in the surrounding country are large quartz veins and schists assaying high in gold. It is possible that profitable auriferous quartz veins will be found in the mountains back of the Lotowana ground. What strikes the visitor, is the enormous amount of quartz of all kinds scattered around the country, not only in the placer itself, but on the top of the hill. The district is distinctly a gold-bearing one, and from a high point the engineer can see in the distance several famous mines, the nearest being the Vulture, which is entering upon a new period of prosperity.

In most placer deposits the rich parts of the dirt are found near bedrock, but here there is a remarkable uniformity of gold content. I found that the mineral carried gold from the grass roots to bedrock. In one pit sampled, about 15 ft. deep, it was noticed that the first 7 ft. went 16 'colors' to the pan, while the lower 8 ft., which ordinarily would carry the most gold, had 11 'colors' to the pan. The reason for this is that the gold has been

form and could not be caught in sluice-boxes, even when mercury was used. If the gold is coated or greasy, it also frequently runs away when sluiced. I know of several placer properties in the United States on which large amounts of capital have been spent which have been dismal failures because the question of whether or not the gold could be caught by ordinary methods was not considered.

Another interesting point in regard to the gravel on the Lotowana mine is the absence of clay. The material is more or less sandy, and is easily disintegrated. There are no big boulders. As the rocks in the 'wash' have not traveled far, they are angular. To handle this material, either with mules and scrapers or machinery, will be simple. Near the Hassayampa river the thickness of the 'wash' increases, and in a few places it is formed into a conglomerate by means of lime infiltration, but as there is a huge tonnage of more available material, this conglomerate need not be touched for many years. Another important feature is the character of the bedrock. When the bedrock is hard it causes much annoyance and damage to machinery; also, there is the danger of losing gold. The bedrock of this placer ground is good, being rather soft and even. It will probably be found that the gold has sunk into the interstices of the bedrock for a distance of nearly six inches, and it will no doubt pay to work off the top of the bedrock. A large amount of black sand is present in the dirt and consists of magnetite and other iron minerals as well as pyrolusite. The black sand is not auriferous.

About 350 to 400 acres of the Lotowana ground has been thoroughly tested by pits to bedrock. The tested area is known as 'Rogers Wash.' There are a number of

other similar 'washes' in the 4000 acres owned by this company which have not yet been tested. One good pit to bedrock for every five acres is often considered sufficient to test placer ground. This would mean that only 60 or 70 pits would be necessary to prove up 'Rogers Wash', but several hundred pits have been in fact sunk. By cutting out a cubic yard of the material and measuring it, it was determined that 140 pans make a cubic yard. By washing a panful of dirt and catching the gold and weighing it, the value per cubic yard is readily calculated. In testing this ground track was kept of all pans, noting the 'colors' to each and carefully saving the gold. The gold was dried with a small amount of black sand and then cleaned by blowing until only the gold was left. This was weighed, and, the amount of material panned to get this gold being known, the value per cubic yard was calculated. The usual method of sampling is to catch all the gold with mercury, then dry off the mercury, and weigh the remaining fine gold. This method would give a higher value than the one used.

In quartz mining it is customary to divide the ore into three heads; positive, probable, and possible. The same division may be used in placer mining. In the Lotowana mine the part known as 'Rogers Wash' can be considered positive ore. It is about  $2\frac{1}{2}$  miles long, averages 1000 ft. wide, and about 9 ft. deep, varying from 1 ft. at the head of the 'wash' to nearly 20 ft. at the foot. In it there is approximately 4,395,600 cu. yd. of material. The average of hundreds of pannings made on this ground is 40c. per cubic yard. There are strips which go far higher, and if the material were selected a large tonnage running 70 to 80c. could be found. But the whole tonnage is profitable and should be worked.

The question as to what the cost will be to work this material is one on which there might be considerable difference of opinion. I estimate it at 10c. per cubic yard. For a few months after starting operation, the cost will be higher, but when the Ledgerwood machines, which it is proposed to use on this ground, get into full swing, the cost should be below rather than above 10 cents.

The 'probable' ore in the Lotowana mine amounts to millions of cubic yards of material. The placer ground in the other 'washes', as already mentioned, has not been proved, but judging from the indications of 'dry washing' and the few tests that have been made, the expenditure of a comparatively small amount of money to dig pits to bedrock would give proof of gravel worth several million dollars. As regards the 'possible' ore, it is my opinion that some day it will pay to hydraulic the high gravel banks on each side of the 'washes'. As there is sufficient material proved to last for years, it is premature to consider the 'possible' ore at this time.

As already intimated, the gold-bearing ground of this property is ideal for sluicing. The only problem to solve to make the mine a big producer is that of water supply. Had water been available, this ground would have been worked long ago. The problem is a difficult one, but can be solved. There are two ways to get water: (1) by building a reservoir and storing the water behind a dam; (2) either by pumping water from the Hassayampa river or building a dam in the river so that the water can be brought to the placer ground by gravity.

The Transvaal is probably the most striking example of the results that can be obtained by storing rain-water for mining operations. Few people unacquainted with the Rand realize that all the water used in that great district is obtained by storing. The same thing has been done in the United States. The success already demonstrated in Arizona in the Roosevelt dam shows what can be done in Arizona. Compared with the Transvaal, Arizona has some disadvantages in the storing of water. In the first place, in Arizona the summer heat is terrific, temperatures of 110 to 120°F. being common during the hot season. Then the dry season is somewhat longer than in the Transvaal. The watershed in the Hassayampa River district, however, is better than the catchment area in the Transvaal. Being

thoroughly familiar with the conditions in Arizona and the Transvaal, I believe in the case of the Lotowana property that the problem can be solved, an ideal site for a dam being available. There are stretches of placer ground in other parts of the Hassayampa River district which cannot be worked with water, for there is no dam-site for miles around. Even if operations could only be carried on for six or eight months at the Lotowana mine with stored water, the running time would still be longer than is obtainable in cold climates like northern Alaska and British Columbia. In my opinion this particular deposit on the Hassayampa river will pay well, even if worked only for eight months out of the year.

There is a good dam-site for the proposed reservoir about 9000 ft. from the head of 'Rogers Wash', and the elevation of the lowest point of the dam will be about 90 ft. above the 'wash', so that all the water will run to the ground by gravity. To build the dam will cost about \$15,000 and the reservoir, when finished and full, will contain between 90,000,000 and 100,000,000 gallons. The path for the pipe-line to 'Rogers Wash' will be sinuous, and a riveted pipe of 10 or 12 in. should be used. During my examination there were three days of almost continuous rain in the district, and I calculated that with the enormous watershed that would direct the water into such a reservoir, the dam would have been running over before the three days' rain had ceased.

Although a small start has been made on the Lotowana property by handling the material with mules and scrapers, it is proposed to install Ledgerwood excavators. These machines have proved most successful in several other parts of the world, as in Siberia and California. The scheme is to run the water from the dam to 'Rogers Wash' by gravity, excavate with the Ledgerwood machine, wash the screened gravel, and catch the water in a small reservoir below the workings and then pump it back to be used over. The same idea is employed in the Transvaal, where the water is pumped back to the mill and used repeatedly.

The question of the cost of power is most important. Fortunately, the conditions for power are good; the Santa Fé railroad running within a few hundred feet of the property, it will be possible to deliver fuel oil by rail. It is proposed to use the Diesel engine for pumping.

A far more ambitious scheme is to throw a dam across the Hassayampa river and use this water for washing the ground. This will be expensive, but feasible. It is locally believed the Hassayampa river cannot be dammed, because years ago an incompetent man put a less competent dam across the river and the floods carried it away; but there would be no difficulty whatsoever in damming the Hassayampa. In order to carry out this scheme, it would be necessary to go up the river eight or nine miles and bring the water through pipes to the Lotowana ground. This scheme will take a lot of money, but it is worthy of careful investigation. From what I saw I believe that it is practicable, and that in the long run it would pay better than to build a reservoir. If the total cost of working can be cut down to 5 or 6c. per cubic yard, there are millions of tons of material running from 12 to 18c. per cubic yard which can be treated.

I fully realize the task of solving the water question in this part of Arizona where the rainfall is never over 15 inches annually, and the evaporation during the summer months is so excessive. While it is true that most of the placer ground along the Hassayampa river is so scattered that there is not a large enough tonnage in one place to justify the expenditure of large sums of money, I know that in the Lotowana and surrounding claims there is sufficient gold to warrant the solving of the water question. If a dam is built on the Hassayampa river, there will be water not only for placer work, but for irrigation as well. Before a careful survey is made, one cannot state the cost of such a project, but the amount of gold in sight is large enough to justify this careful survey. It is my belief that it will show that the scheme of getting water from the Hassayampa river is feasible.

## The Katalla, Alaska, Oilfield

By ARTHUR THOMPSON

Few people in the United States know that there is an area extending along the coast of Alaska for more than a hundred miles which contains petroleum. In fact, the Alaska coast land eastward from the Copper river delta almost to Icy bay, at the foot of Mount St. Elias, is underlain with oil-bearing strata. Hundreds of seepages of oil are scattered along this belt and extend some distance back from the sea. It is not generally known, even in Alaska, that there are producing oil wells at Katalla, near the western end of this oil belt, and that these have been yielding petroleum of an especially high quality for more than a year, and that a little refinery situated near

dova, and Valdez, where it is in great demand for use in launches and in gasoline engines on account of its high efficiency, being preferred to the gasoline imported from the states. Valdez, which is the centre of a prosperous gold and copper mining region, has a dock controlled by the municipality, where the Alaska gasoline is given a half rate, the wharfage charge being 50c. per ton on local gasoline, and \$1 on the imported article.

These facts are significant. They indicate that the coal of the Bering river and the Matanuska fields, when finally put upon the market, may have a strong competitor in the native oil of this same region. This crude oil is too

OIL SEEPAGE NEAR KATALLA.

OIL WELLS AT KATALLA.

the wells has been making gasoline and kerosene from this oil. The westerly or Katalla part of this oil belt was reconnoitred by G. C. Martin, of the U. S. Geological Survey, in 1906, and was reported as oil bearing and favorable for exploration. This report,\* including maps of the region, was published by the Government, and may be obtained of the United States Geological Survey at Washington, D. C. The larger area to the east has never been explored by the Government geologists. In it are many large seepages and other favorable indications of oil.

Analysis of the oil shows that it has a paraffine base and contains about 38.5% naphtha and gasoline, and about 31% of kerosene, the remainder being paraffine and lubrication oils of high quality. The petroleum produced from these wells contains such a high percentage of the lighter volatile oils that persons sending out samples have been accused of 'doctoring' the oil. Gasoline produced at the local refinery is shipped to the coast towns, Katalla, Cor-

valuable to use as a fuel as it comes from the wells. Two-thirds of its content may be taken out in gasoline for use in gas-engines and kerosene for lighting, and the remainder may be sold for fuel purposes, or it may be still further refined, yielding valuable lubricating oils, heavy greases, paraffine, and many by-products. It is worth several times as much per barrel as the fuel oil of California. While the oil world may look more or less complacently upon the opening of a new field in California producing a heavy asphalt oil, there will be a great oil excitement and an unprecedented period of development in this part of Alaska when further exploration shall demonstrate, as I believe it will, that there is a vast oil belt in Alaska which contains an incalculable amount of the finest petroleum in the world.

The Alaska coast, along which this oil belt lies, is skirted by a low range of mountains from 1000 to 2000 ft. high, which rise abruptly from the coastal plain a few miles from the sea. Along the base of this range, upon the seaward side, and extending up the 'draws' and gulches to the top of the range, are hundreds of seepages of oil. It

\*'Geol. and Min. Res. Controller Bay Region, Alaska,' Bull. 335, U. S. Geol. Survey.

is thick and dark green in appearance, the volatile gases having largely evaporated. It will burn fiercely when a match is applied, but this is a rather dangerous experiment on account of the large amount of gas around these seepages. They are numerous on each side of Katalla, for a distance of about 30 miles; also for about the same distance eastward from Yakataga, at the eastern end of the belt. The mountains of this range are composed of alternating strata of sandstone and shale, with a few strata of conglomerate. The mountains in the Yakataga section rise somewhat precipitously from the coastal plain on the seaward side, and the alternating strata of white sandstone and dark shale rock, having a strike parallel with the range itself, give the range a beribboned appearance for miles which is very striking. The territory between the Katalla and the Yakataga sections is occupied in part by the wide alluvial deposits of several glacial rivers, which issue through brakes in the mountain range and have their sources in the main Alaska range, 30 to 50 miles back. The evidences of oil are not so abundant here, although

(Martin, U. S. Geol. Surv.)

#### KATALLA OILFIELDS.

seepages are found in these river valleys upon the farther or northerly side of the coast range, some 10 or 12 miles from the sea.

Along certain portions of this range for miles seepages occur in every gulch and 'draw,' forming small pools and dribbling rivulets of oil. In places whole mountain-sides at the base seem to be saturated with the oil, evidences of which can be found by digging to bedrock almost anywhere. Some streams, such as Johnson creek, carry so much oil down to the sea that its iridescent colors can be seen on the surface of every pool and eddy, and the peculiar odor of the oil can be detected half a mile distant when approaching the stream. There is a little lake of oil near the head of this stream. In winter the freezing of the water causes the stream to rise and fall between its banks of snow, which become saturated with oil for a distance of two or three feet, vertically, giving a peculiar yellowish color to the snow. In places gas rises with the oil, and in many places there are gas seepages where no oil appears.

The inhabitants of this section find the oil useful for many purposes. At Yakataga an auriferous sea-beach has afforded a living for a little community of miners for many years. Some of these men have set barrels in the seepages, which are so arranged that the water is discharged and the oil remains. They find the oil convenient for building fires; they also use it for lubricating and other purposes.

At Mirror slough, in the extreme western part of the Katalla region, there is a large gas seepage, which, when lighted, will continue to burn till the tide comes in and extinguishes it. The fresh oil from the wells is very explosive, and may be lighted with a match held at some distance from the oil.

Preparations are being made at Katalla for a more extensive prospecting of the field. The oil thus far obtained comes from a stratum not far below the surface of the ground, though some of the wells have penetrated below this. It is thought by many that this oil has worked its way up through crevasses and cleavage in the formation and has spread its way through the receptive sandstones near the surface. It is believed that deep drilling will be necessary to determine the source of the oil supply. Owing

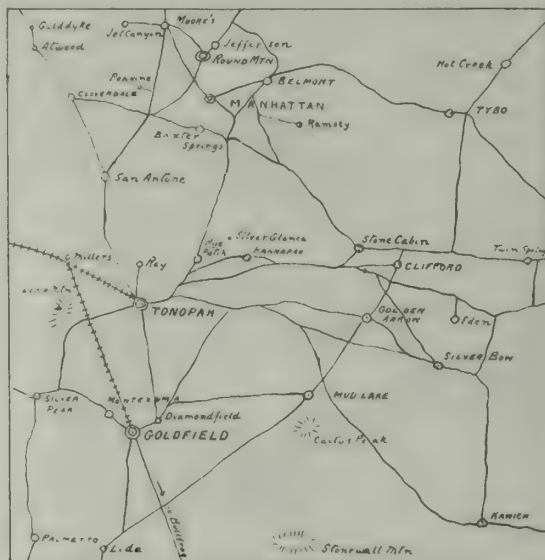

to the large amount of gas made by the wells, and the pressure, it is thought that when the oil is found at depth, it will be under great pressure. It seems certain that an oil belt of this extent, where probably hundreds of barrels of oil are thrown off by seepages every month, must have a large body of oil behind it.

### Antelope Mining District of Nevada

This district, which takes its name from an important group of springs, is about thirty miles east of Goldfield, in the southern part of the Cactus mountains, one of the desert ranges, between 6000 and 7000 ft. in elevation. It is connected with Goldfield by good wagon, automobile, and stage lines. The district was examined last January by F. C. Schrader, and the U. S. Geological Survey has just issued a brief report (Bull. 530-J) upon the district, written by him.

Gold was discovered here in 1903, when the region was visited by a wave of prospectors that followed in the wake of the Tonopah boom. Since that time several isolated prospects have been held, but the discovery of high-grade ore which caused the formation of the present camp was made in November 1911. Soon after that date there were more than 150 men in the district prospecting and making locations, and by the close of the year, a \$15,000 five-day option had been taken on the discovery claim.

When Mr. Schrader visited the district two townsites were being developed, supplies and machinery coming in,

MAP SHOWING SITUATION OF CACTUS PEAK.

some ore was being hauled out, and considerable ground had been opened, but development was still confined to the 'oxidized' zone. The discovery shaft at that time had reached a depth of 23 ft. and practically all the material excavated from it—about 30 tons—was ore that averaged about \$200 per ton, and contained some rich bunches. The deposits are silver and gold, which are found in or associated with veins and fissures in the rhyolite. The veins are about 20 in number, ranging in width from 1 to 20 ft. Some of them are persistent and have a known extent of 2000 or more feet. The valuable ore minerals are chiefly horn silver, argentite, and gold. Four-fifths of the value is in silver and one-fifth in gold. Some of the ore contains considerable free gold, which may be extracted mechanically in panning. The light color of this gold indicates that it is alloyed with native silver. According to latest accounts, received in April, the outlook for the district is encouraging. The 'main strike' shaft had at that time attained a reported depth of 85 ft., with continuation of the ore favorable in amount and grade. Good ore has also been found at several other places, and plans are made for the early building of a mill.

## Mine Fire Protection

Serious consideration of the problem of protecting mines from fires has been undertaken jointly by the National Fire Protection Association and the United States Bureau of Mines. The inquiry is under the direction of a committee consisting of H. M. Wilson, R. Y. Williams, Albert Blauvelt, J. Parke Channing, Washington Devereux, B. W. Dunn, Ira H. Woolson, J. W. Paul, and R. V. Norris. Appointment of this committee was authorized at the fifteenth annual meeting held in New York, May 23, 1911. The committee held its first or organization meeting in Pittsburg, Pennsylvania, November 1, 1911, and a second meeting in New York, January 16, 1912.

When the National Fire Protection Association entered the field of mine fires through the appointment of this committee, it found the United States Bureau of Mines actively engaged in field investigations, study, and tests relative to this subject. The composition of this committee was carefully considered with a view to securing among its membership engineers of the United States Bureau of Mines, prominent mining engineers in private practice, and fire protection engineers familiar with what has been done in this field of endeavor in connection with fire risks in buildings and factories.

In view of the above condition, it seems to the committee desirable at this time that the entire problem be completely outlined, and this has been done in the following schedule with a view to having this committee consider and report upon those features toward which the experience of its several members can most readily contribute, leaving to the United States Bureau of Mines to consider those problems which call for statistical inquiry, field investigation, or laboratory test, and toward which the expert knowledge of the mining and mechanical engineers and chemists employed in that Bureau can best contribute.

With a view to making recommendations which will call for the outlay by mine-owners of the least sum in protecting their property, the committee has prepared the schedule below, arranged in such manner that the details will be easily apparent to the busy mine manager and will indicate to him those things concerning which he may seek further information of this Association, and those things regarding which this Association is not qualified to help him and on which he should seek advice from the Federal Government. Suggestions and recommendations on any of the points mentioned will be welcomed and should be addressed to the secretary of the committee, R. Y. Williams, at Urbana, Illinois.

In presenting the following outline, this committee disclaims any right or authority to speak for the United States Bureau of Mines other than to indicate those matters which this committee believes it can best investigate and which it proposes, with the consent of the Association, to investigate and report on in greater detail hereafter, and on the other hand, those things regarding which it should give no further consideration, believing that it has not the facilities to investigate them and believing that the United States Bureau of Mines is better qualified to consider them.

### STATISTICS

*By Committee.*—Recommendation as to the nature of inquiry, character of data desired on loss of life, injury to life, loss of property, losses inside and outside, losses in mineral matter, origin of fire, etc.; also a comparison of mine fire statistics, foreign and domestic.

*By Bureau of Mines.*—Collection, tabulation, discussion, and publication of statistical data.

### PROTECTION OF SURFACE PLANT

All surface works are capable of precisely the same treatment as other non-mining property. Any works built at mine openings should unquestionably be non-combustible; all works should be protected, probably most advantageously by automatic sprinklers.

*By Committee.*—Building materials to be classified in a general way only, as (1) non-combustible buildings with non-combustible contents, and (2) other buildings, whether combustible, or not containing combustible contents. Danger from outside fires: Brush and timber should be cleared to a distance of at least 100 ft. from opening. Inflammable buildings should be at least an equal distance from opening. If possible, area immediately over opening should be fire-protected by construction of non-inflammable structures in such manner as to isolate the opening from inflammable structures. Such structures over opening to have permanent metal awnings protecting window and door openings against blown firebrands. Grouping of buildings to be dependent on materials of construction. Distance of explosives magazine from nearest building and from opening to be based on recommendations published by Bureau of Mines. Water-supply for outside protection to consist of a big tank or storage reservoir of a capacity of from 30,000 to 100,000 gallons and placed on a tower or hillside at elevations from 125 to 200 ft. Such elevations will furnish constant service and good pressure for hose for fire-pumps. If domestic water is taken from such tank, it should be taken from a pipe from a domestic outlet near the top, so as to leave at least 80% of the tank as a constant head for fire-protection reserve. Where the condition of the buildings permits, the most positive means of fire protection is by automatic sprinklers, and their installation and operation is fully covered by regular sprinkler rules of this Association. Self-inspection of buildings is recommended by the display of information printed in large type and posted in protecting frames after a manner recommended by the Factory Insurance Association.

*By Bureau of Mines.*—Construction of special devices for preventing spread of serious fires to underground workings, as special steel doors, protection against introduction of fire through surface caves or outcroppings, protection against incendiarism.

### CONSTRUCTION OF MINE OPENINGS

*By Committee.*—Extent, amount, and head of water-supply; automatic sprinklers for shaft protection; automatic sprinkler systems probably less expensive than elaborate cut-offs or fireproofings for combustible stables, store places, engine-houses, etc. These, however, if placed in shafts or shaft bottoms, would doubtless reverse the draft and would be beneficial if down-draft were desired, but fatal if up-draft were desired, to the safety of the men.

*By Bureau of Mines.*—The nature of materials best suited to the requirements of mine operation through the shaft or opening, having in view fire protection, safety of exit, etc. Such openings should be incombustible throughout, in order to obviate the need for and danger inherent with sprinklers.

### UNDERGROUND WORKS

*By Committee.*—Water-supply for fire protection; possible quantity required; head desirable. Water-supply for surface works and water-supply for underground works are dissimilar problems, and should preferably be separately provided for and not be interconnected. For underground works, the water-supply should be ample and preferably stored underground, thus avoiding trouble from hydraulic head, signaling service, or freezing.

Water-supply for the automatic sprinklers proper may be limited in quantity if stored in a pressure tank under high pressure. For limited spaces such as store-rooms and stables, there is no record of fires which 3000 gal. of water under pressure has failed to extinguish. Including the necessary air, a pressure tank of 4500 to 6000 gal. should be adequate. This, applied to local pieces of sprinkler equipment as for store-room or stable, would call for space ranging from 5000 to 10,000 sq. ft. area.

For pump supply which may be called upon to supply hose streams for long periods, the quantity of water is a different matter. As much as 250,000 gal., which amount may be stored in a relatively small space, will run a number of hose streams as heavy as can be handled by one man

for a number of hours; for example, 125 gal. per hose stream per minute would mean a  $\frac{7}{8}$ -in. nozzle for 2000 minutes, or 10 such streams for more than 3 hours.

*By Bureau of Mines.*—Consideration of inflammable underground works and structures; relation to fire originating outside, relation to fire originating inside. Consideration of types of construction with cost data for fireproof construction and for fire-resistant construction, inflammable construction; handling and storing combustibles, such as hay, oils, explosives, and cotton waste. All inflammable material should be listed, quantities allowable in the mine at one time stated, nature of containers specified. Methods of storing oils, protection of steam-pipes, electric wires, design and construction of special fire-doors, possible use of fusible links for doors, even though of wood, use of fusible plugs for holding doors open. Doors, if closed and automatically wet by a sprinkler, may serve as a fire stop.

#### LIVE WORKINGS

*By Bureau of Mines.*—General rules and precautions for protection from lamps and lights, candles, wicks, careless handling of oils and explosives, gas-blowers, black powder flame, electric wires, and ignition of coal dust.

#### ABANDONED AREAS

*By Bureau of Mines.*—Isolation from live workings by separate return air ventilation, or by sealed fire-resistant walls; type of construction of same; precautions and special inspection for gob fires and from accumulation of gas and of water.

#### SPECIAL UNDERGROUND CONSTRUCTION

*By Committee.*—Fire extinguishment; consideration of relative efficiency of various pumps; possible centrifugal pump taking water under head and operated by induction motor will give better satisfaction because it is easiest operated by unskilled men, and may be put in service from a distance by signal wire or telephone. Study should be made of quantity of water required, size and construction of pipes, nozzles, and styles of fitting. For working in confined space of a mine in presence of heat and gases, heavy hose streams would seem impracticable, probably nothing in excess of  $1\frac{3}{4}$  to  $1\frac{1}{2}$  in. taken off a 2-in. line, or from long distance from source of supply, 3 or 4-in. line, as indicated by distance and friction head. Consideration of extra parts and their availability; protection from frost near surface entries and supervisory inspection of fire service; fire extinguishers and chemical engines and trucks should be considered. Probably small extinguishers of portable type, and many of them, most useful in incipient fires; a few larger chemical engines desirable for fighting fire after it has gotten under headway.

*By Bureau of Mines.*—Mine timber; dangers incident to the use of wooden timbering, and the possibility of replacement of these by such fireproof timbering or lining as brick, reinforced concrete, or steel; question of fireproof paint or solutions for timber, though these are not believed to be effective; possibility of coating wood timber with cement gum.

Power; rules for use; electricity for lights, motors, and machines; steam locomotives and engines, boilers, and heating furnaces; compressed air, oil, and gasoline engines.

Stoppings; classify by fire resistance and action on same of explosions, namely, wood, gob, tamped clay, dry walls, wood fibre coatings, metal lath and plaster, reinforced concrete, brick, and masonry.

Overcasts; classify with cost data: wood, masonry, concrete, brick, and combinations. Fire-fighting materials; life of various kinds of hose in mines and method of installing and protecting underground; use of air-pipes as emergency water mains; friction developed and quantity of water discharged through pipes and nozzles; head of water for varying depths; efficient throttling and reducing valves for great depths; relative efficiency of various pumps for underground use.

Fire-fighting methods: by smothering; by surrounding or cutting off; flooding; loading out hot ashes, etc.; flushing with sand, earth, etc.; refuge chambers and safety sup-

plies; equipment; possible advantages of chambers, their design, location, and number; use and types of rescue apparatus; extent of supply and training.

Fire corps: special training of corps for rescue, first aid, and fire-fighting; rules and methods of training; volunteer fire corps; organization, stations, and drill.

Fire alarm signaling systems; telephones probably best; alarm duty by workers; escape maps, their construction, scale, objects to be shown, and their location and availability.

## Alaska: A Condition and a Program

By WALTER E. CLARK

\*Greatly as we may deplore the present conditions, we cannot expect a remedy by merely denouncing them. A great many Alaskans and the leading members of the national administration realize this. At the beginning of the controversies produced by the application of a counterfeit policy of conservation to the coalfields, residents of the territory were far from being agreed as to the remedies to be applied. At first, the proposition to lease the coal lands was a bone of contention; and the proposal to build a Government railroad was opposed by many. Very recently there has been a distinct precipitation of public sentiment in the territory favorable to any plan upon which the authorities at Washington may agree. With the majority now the desire is not to dispute as to just how the fuel and transportation questions should be settled, but that those questions be settled somehow and quickly.

A program of legislation to relieve the present disheartening condition in Alaska has been pretty thoroughly worked out by the administration. I refer, first, to certain minor measures of proposed legislation. It is a singular fact, not at all creditable to the nation, that nearly 45 years after the occupation of Alaska by the United States, there are wanting for the government of this territory several elementary provisions of law which are found in every other part of the civilized world. There is no means of establishing a quarantine in Alaska, except by the means of a somewhat strained construction of the laws governing the Marine Hospital Service, and no adequate means of preventing the spread of contagious diseases; there is no law providing for the supervision and control of banks and banking, although there are many banks in the territory; there is no provision for the registration of births, marriages, and deaths, although the absence of such records often causes grave injustice and human suffering; there is no public means of relieving indigent persons. It is a part of the program of the present national administration to fulfill these wants, and it is hoped that the Congress at Washington will pass the necessary measures, which have been urgently recommended. Through the lack of such ordinary and usual provisions of law as these, the development of the territory is discouraged to a considerable extent, although the greatest obstacles are due, of course, to the failure to provide certain more important measures of legislation.

The larger measures—those pertaining to the coal lands and to transportation—are now, as they have been for too long, the subject of much difference of opinion. It is not necessary to decide which of these subjects is the more important; both are vital. The coal is worthless without railroads to transport it; the railroads would be far less profitable without the coal for tonnage as well as for engine fuel. If one must choose, the transportation question is probably the more vital of the two; but nobody doubts that the settlement of either will lead speedily to the settlement of the other.

The President, Mr. Taft, has endorsed the proposal of

\*Abstract of a recent address by the Governor of Alaska, as printed in the *Cordova Daily Alaskan*.

the Secretary of the Interior, Mr. Fisher, that at least one trunk line of railroad, tapping one of the principal coalfields and connecting one of the navigable rivers with tidewater, be built by the Federal Government. Within a few months after he took charge of the Interior Department, Mr. Fisher visited the coast of Alaska and one of the principal coalfields as well as the upper navigable waters of the great Yukon river, and there received visual testimony as to the importance of both transportation and the fuel problems. His conclusion to recommend that the United States should construct one arterial line of railroad in Alaska was not reached without a very deliberate and painstaking study of the subject, and not without consideration of the fact that many persons doubtless are constitutionally opposed to Government ownership of transportation lines. The conditions in Alaska he regards as peculiar, and moreover, he pertinently cites the fact that the Government owns and operates the Panama railroad and will own and operate the Panama canal. As to the instrumentality by which the proposed Government railroad in Alaska shall be operated, the administration has

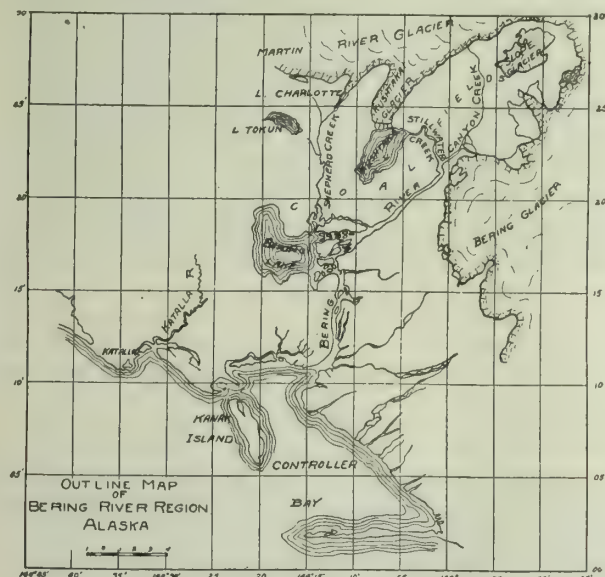

ing in our northern territory and used in construction.

Views as to the settlement of the coal-land question have been somewhat clarified in the past six months, although these have not yet crystallized into action. Described in general terms, there are but three possible means of opening up the Alaska coalfields so that this rich store of fuel may be available for the people of Alaska and the several uses of the Pacific Coast, including the United States Navy. First, private ownership of the coal-bearing areas in fee simple, under the terms of a reasonable law of Congress yet to be enacted; second, continued public ownership of the lands, and the mining of coal under leases by private persons; third, continued public ownership and Government operation of the mines. It is pretty generally recognized that Congress is not likely to pass an improved law authorizing the patenting of any more coal lands—at least not unless there should be a decided and unlooked-for change in the present state of public opinion. Government operation of coal mines plus ownership of the lands is hardly likely to be adopted as a national policy, in the near future at least. This leaves the leasing system as the only practicable means likely to find favor with the representatives of the people. At this writing no bill fully representing the administration's views regarding a leasing system has been introduced in Congress. Presumably, such a measure will be introduced as soon as there is a prospect that it will obtain consideration. Then the problem will be to reconcile the views of those who entertain the fear that a monopoly will result under any plan which may be adopted for the mining of Alaska coal and the wishes of those who believe that almost any condition would be better than the present state of stagnation and deprivation.

While the interests of the public must be regarded as paramount, it is well to bear in mind that a due regard for the rewards which capitalized enterprise is entitled to obtain from its operations must be observed in the framing of any coal-law for this territory.

As I have already indicated, the *sine qua non* of early prosperity and settlement in Alaska is a more considerate attitude on the part of the Congress of the United States, and to some extent on the part of the press and people of the United States, toward the territory. This improved attitude should consist, among other things, of a clearer discernment of the rights of highly capitalized interests. The main resources of the district were so securely locked up by the forces of nature at the beginning of the world that they never can become productive unless expensive means of operation are provided. To keep capital out for fear of monopolies is not worthy of American courage in the first instance, and in the first and last instances it is to beg the whole question of territorial development and progress.

The great territory comprised in the Seward purchase will in the years to come be the abiding place of a people much more numerous than those who reside there at present, although I am not among those who prophesy a population of several millions. The natural conditions do not promise great density of population, and will never encourage it unless the circumstances affecting human migrations and modes of life shall be greatly changed during the progress of the world in the next century. But the territory is a healthful place of residence, whatever may be the popular misconceptions regarding its climate; the mines and the forests and the fisheries are at the beginning of their productiveness; the agricultural lands invite settlers as hardy and thrifty as millions of those who inhabit northern Europe; the opportunities of the future in many walks of life will be countless for those to whom work is gospel. A territory with such riches and opportunities, but so sparsely settled as it is at present, does not need many new laws; but further neglect to enact those few primary measures which alone can cause the proper development of the natural resources and bring to the territory a larger number of happy and prosperous people to enjoy them, must be regarded as discreditable to the nation.

ONE OF THE ALASKA COALFIELDS.

not expressed an opinion. The question whether the Government shall operate the railroad or lease it to an operating company may be left to Congress. My own opinion is that many of those persons who are opposed to Government ownership and operation of railroads, on general principles, may look with complacency upon the building of a Government road in Alaska, in consideration of the special conditions there, especially if it be decided that the Government shall leave the operation of the road to a private company under the terms of a lease acceptable to the Government and calculated to conserve the interests of the public. Federal aid for the construction of railroads has been extended in various forms, notably in the form of land grants and by a guarantee of interest on bonds of indebtedness within a certain maximum limit per mile. If the Government itself should build the main trunk line in Alaska and then lease the line to an operating company, the cost of construction might reasonably be regarded as another form of Federal assistance for such construction, not differing in the first principle from a land grant or an interest guarantee. Unquestionably, the selection of a route for the proposed railroad should be left to a board of engineers to be appointed by the President; and our treatment of the Panama canal question might be followed further by placing the construction of the road in the hands of the Corps of Engineers of the United States Army. Mr. Fisher, who has recently visited the Isthmus as well as Alaska, has made the suggestion that a part of the equipment used in building the canal be transferred to the scene of proposed railroad build-

## The Situation in the State of Chihuahua

By AN OCCASIONAL CORRESPONDENT

The city of El Paso, Texas, is at present (July 30) filled with people who are keenly interested in the Mexican situation. Refugees, mostly women and children who have been sent out for safety, and men who have been on vacations in the states and are on their way back to work, soldiers, secret service men, and newspapermen are all anxiously waiting for news from across the river. The number of refugees is being daily augmented by the arrival of families of Mormon colonists. Although authentic news is scarce and much misinformation is given out, the facts of the situation seem to be that a trip from El Paso to Chihuahua is a very uncertain and difficult undertaking. A few men have managed to get through by way of Eagle Pass and Torreon, while others have returned after getting as far as Torreon. Between that point and Chihuahua there have been frequent interruptions of traffic from raids of small rebel bands left behind the main Federal forces. A few parties have gone through by automobile, equipped with passes from Orozco, but not many can get these passes. Orozco is still in possession of Juarez with a few hundred men. He derives what revenue he can from the customs, and what assistance he can from his agents in El Paso, which is probably very little on account of the vigilance of the United States authorities. Orozco is supposed to be watching his chance to slip across the border, but he is likely to be foiled if the attempt is made, as the secret service men are watching closely for him. His only chance for escape is to get into Sonora before the Federal forces arrive at Juarez. To delay the advance of the Federals as much as possible, the Mexican Central midway between Chihuahua has been completely demolished. From excellent authority I have learned that not a vestige of the track remains for 50 kilometres. The ties and bridges have been burned, the rails twisted, and the fish-plates, bolts, and spikes carried away and hidden. It will be months before traffic can be resumed on this line.

Trains have been running regularly on the Mexican Northwestern through Juarez as far south as Madera, and an occasional train has gone on to Tamosachic. Between the latter point and Chihuahua the rebels have burned and dynamited a number of bridges. The Federal forces, which are slowly advancing northward from Chihuahua along the lines of the Central and Northwestern, are repairing these roads. The smelters of Chihuahua are closed for lack of coke, and the mines are very short of explosives. I do not consider the lives of American men in danger, and their personal property outside of livestock and firearms is not likely to be molested. On account of the uncertainty, however, most of the women and children have been sent out of the state. The situation of the rebels is desperate, and they are helping themselves to what they need. Armed resistance on the part of Americans to such depredations is worse than useless, as the Mormon colonists are finding to their sorrow.

Desertions from the rebel army must have been heavy during the past two weeks, as it is difficult to account for more than half of the force that retreated northward from Bachimba. The largest force seems to be at Dolores, where Rojas has about 2000 men. Garrisons of about 200 each remain at the towns of Casas Grandes, Pierson, and Madera, with a few at the stations farther south, while several hundred have gone into the Ocampo district over the Greene wagon-road. These forces have stocked up on clothing and supplies, and taken the available horses and mules from the towns en route. In some cases they have seized pack-trains and dumped off loads of high-grade concentrate by the trail, and Rojas, on his arrival at Dolores, seized one store and blew open and rifled the safe. All this resembles banditry more than warfare, and renders it impossible to carry on any business while it lasts. The revolution might have been ended before this,

if the Federals, after their victory at Bachimba, which was largely due to the use of artillery, had followed closely on the retreat of the rebels northward, giving the tired and hungry fugitives no time to recuperate or stock up with supplies. Instead, the rebels have been allowed to get into the mountains, where they can carry on brigandage until they are hunted out. It seems to be significant that these various bands are getting near to their old haunts again, so when they are hot pressed it will only be a matter of changing clothes, and hiding their guns, until they become plain *hombres* again. They can then seek work at the very mines they are now trying to despoil. The strongest hope for a speedy settlement of the trouble lies in the reported appointment of Gen. Trucey Aubert to the command of the northern Federal forces. Gen. Aubert, who is part French, has the reputation of being the best fighter in Mexico, and a strong hand will be needed to end the brigandage.

The present situation is so exasperating to those interested in the welfare of Mexico that almost any move that would end this hopeless rebellion would be welcomed.

## Examination For Mine Technologist

The United States Civil Service Commission announces an examination to fill a vacancy in the position of mine technologist in the Bureau of Mines, field service, at a salary ranging from \$1800 to \$2400 per year, and vacancies requiring similar qualifications as they may occur, unless it is found to be in the interest of the service to fill the vacancy by reinstatement, transfer, or promotion. The duties of the person appointed to this position will be a general study of mine conditions with reference to economic problems with a view to the improvement of these conditions, especially in the coalfields of the United States, and a study of these conditions as affecting the welfare of the miners. Qualified persons who desire to be considered for this position should apply for Form 304 and special form to the United States Civil Service Commission, Washington, D. C.; the secretary of the board of examiners, postoffice, Boston, Mass., Philadelphia, Pa., Atlanta, Ga., Cincinnati, Ohio, Chicago, Ill., St. Paul, Minn., Seattle, Wash., San Francisco, Cal.; custom-house, New York, N. Y., New Orleans, La., Honolulu, Hawaii; old custom-house, St. Louis, Mo.; or to the chairman of the Porto Rican Civil Service Commission, San Juan, P. R. No application will be accepted unless properly executed and filed with the Commission at Washington, in complete form, with the material required, prior to the hour of closing business on August 24, 1912. In applying for this examination the exact title as given at the head of this announcement should be used in the application.

SULPHUR is found in Colorado, and some effort has been made to work the deposits, according to a report issued by the U. S. Geological Survey (Bull. 530-O). The principal deposits are in Mineral county, Colorado, about 25 or 30 miles southwest of Creede. One of these deposits is on Trout creek, about 25 miles southwest of Creede, and is reached by wagon-road that is good over most of the distance. The available data on the deposits as exposed in the tunnels indicate that it is a surface deposit about the opening of a series of hot springs. The greatest observed thickness of sulphur rock was about 16 ft. A mill was operated for only a short time and it is believed that little or no sulphur was placed on the market. The other deposit in this section is about five miles south of the workings on Trout creek, and is similar in all respects to the sulphur-bearing mass at that locality. The deposits are believed to have been made by the hot springs.

THERE were 661 mines producing gold, silver, copper, lead, or zinc in Nevada in 1911, compared with 608 in 1910. Of these, 72 were placer mines. The total quantity of ore sold or treated in Nevada in 1911 was 4,132,721 short tons, an increase of 476,946 tons.

# The Waihi Company in 1911

The twenty-third annual report of the above company contains a mass of interesting information in its 83 pages; and while details are full, the report is not overdone. Year after year the output had increased until 1909 showed £959,594, and another year or so at the same rate of increase would have seen a total of £1,000,000. In 1910, the ninth level became poorer, and the yield dropped to £926,100 from 442,020 tons. The year under review showed a drop to £679,113 from 350,669 tons. The main features of the report may be summarized as follows: The development of the tenth level has been disappointing, especially on the

silver to gold in ore was about 7 to 1. From 1,067,432 oz. bullion recovered from all sources, the refinery produced 137,195 oz. gold, and 939,621 oz. fine silver. Many experiments were tried during the year, and the assay office dealt with 17,475 samples of various kinds. The foundry at Waikino dealt with 301½ tons of iron castings, 77 tons of steel, and 4¼ tons of gunmetal, and repairs are effected quickly and cheaply. The Hora Hora hydro-electric power works were pushed on as fast as the weather and delivery of parts would allow. The erecting of the steel towers for the 51 miles of transmission lines is under way. It is expected that power will be delivered within twelve months. At the time of writing, the Waihi mine and mills are shut down, as the result of a difference of opinion between the engine drivers and miners' union, and an attempt to drag the company into the argument. The water is not rising very fast in the mine. The strike may be a long one, and being so trivial it is very unfortunate for both the shareholders and the majority of the men employed.

THE MAIN STREET AT WAIHI.

WAIHI, NEW ZEALAND, NOW BEING DEPOPULATED ON ACCOUNT OF THE STRIKE.

Martha lode, but an active exploratory campaign will be continued. The shafts in working order were 1080, 1150, 1181, and 1023 ft. deep, respectively. Seven filling passes were in use, and 250,738 tons of material was put into the stopes. Waste rock hauled amounted to 12,160 tons.

The two mills of 90 and 200 stamps, respectively, were operated during the year, the Union mill of 40 stamps being sold after working 26 days. The Waihi mill averaged 5.14 tons per stamp daily, and the Victoria 4.94 tons through a standard 10-mesh screen. An average of 3.8 tube-mills worked in the first, and 8.2 in the second mill. In all, 5368 tons of concentrate was produced, representing 1.53% of the total ore crushed. The average value of this product was £21 13s. 9d. per ton, and its residue after tube-milling, air agitation, and filter-pressing was worth £1 1s. 7d. per ton, showing 95% extraction, at a cost of 25s. 1d. per ton of concentrate.

The head assay of the ore was 42s. 10d. per ton, the residue 4s. 8d, showing 89% extraction. The proportion of

WHITE ARSENIC was produced in the United States in 1911 to the amount of 3132 tons, valued at \$73,408, against 1497 tons, valued at \$52,305 in 1910, according to a report on arsenic by Frank L. Hess, of the U. S. Geological Survey. The arsenic was obtained as a by-product of smelting operations. This output is much the largest ever made in this country, but owing to the low price and the distance of the smelters from New York, the freight charges absorbed a large proportion of the profit. During the year 4996 tons of white arsenic, metallic arsenic, and arsenic sulphides, valued at \$247,323, were imported. Of this amount, 1921 tons was white arsenic, with a value of \$116,948.

## Transvaal Mine Supplies

By FRANCIS DRAKE

The annexed list of some of the supplies consumed in the Transvaal during 1911 should prove of interest to all those connected with mining. Probably the quantities will be somewhat of a revelation to many. The list is not complete; only items of special interest are included. The total values are: for gold mines, £11,707,286; for diamond mines, £271,219; and for coal and other mines, £481,776; making a grand total of £12,460,281.

In the gold mines during the year 24,456,821 tons of ore was milled, yielding 8,237,723 oz. of fine gold worth £34,991,620. In doing this, an average of 205,000 natives were employed. Taking these figures with those in the tabulation, it will be seen that for each ounce produced \$6.90 was spent in supplies. Working it out at per ton milled, the amount paid out in supplies comes to \$2.30. Just under one-half pound of candles was consumed per ton milled, and almost the same weight of cyanide was consumed. Somewhat over 0.6 lb. of shoes and dies was used per ton of ore milled. Slightly more than one-half pound of drill steel was used per ton milled, but it must

be remembered that this material was also used in doing various kinds of 'dead' work. This remark will also apply in considering the quantity of explosives used, which amounted to nearly 1.4 lb. per ton milled. The quantity of zinc consumed per ounce of output was slightly over 1 lb. This does not represent the quantity used per ounce recovered in the cyanide process, however, as a large portion of the gold output is recovered by amalgamation. The feeding of the native workers was quite an undertaking, the total amount spent under this head being £1,033,625, a little over 20c. per ton milled. Note also the expenditure for beer-making materials and medicines, these amounts being for natives.

Turning to the diamond, coal, and other mines, it is worthy of consideration that they used explosives of a lower grade than the gold mines, and that the diamond mines had no rock-drills, although they used a notable quantity of hand-drill steel.

The Oregon and pitch pine was supplied from the United States, and this is of interest when sea and land transport is remembered. Many other items on the list give food for thought, as does the total amount for all supplies for all mines, which is equal to over \$200,000 per day, taking 300 for the number of working days in the year.

## High Grade

A recent visitor to this district in Modoc county, California writes:

"The High Grade district is in a prospective state at present, and it is rather hard to tell what the result will ultimately be; but the surface looks very favorable to me, and I am of the opinion that with some systematic development it will make a mining camp. There are at present several very likely-looking prospects. The Consolidated has recently opened a vein 160 ft. below the surface, which shows 4 ft. of ore averaging over \$150

per ton. At the Lucy Dutchman lease there is ore which assayed as much as \$1480. The average across 3 or 4 ft. will probably be about \$60. The Modoc has 2 ft. of \$50 ore at a depth of 50 ft., and is situated 3½ miles from the Consolidated. This makes the mineral-bearing area fairly extensive. At the Sunshine they are following a stringer about 6 in. wide which is very rich, and especially is this true of the mud ore found with the quartz. I think I am safe in saying that the ore from this vein will average \$400. Mining facilities are almost ideal. Timber, water, and produce are procurable in abundance. It certainly looks good to one who has had a few years on the desert."

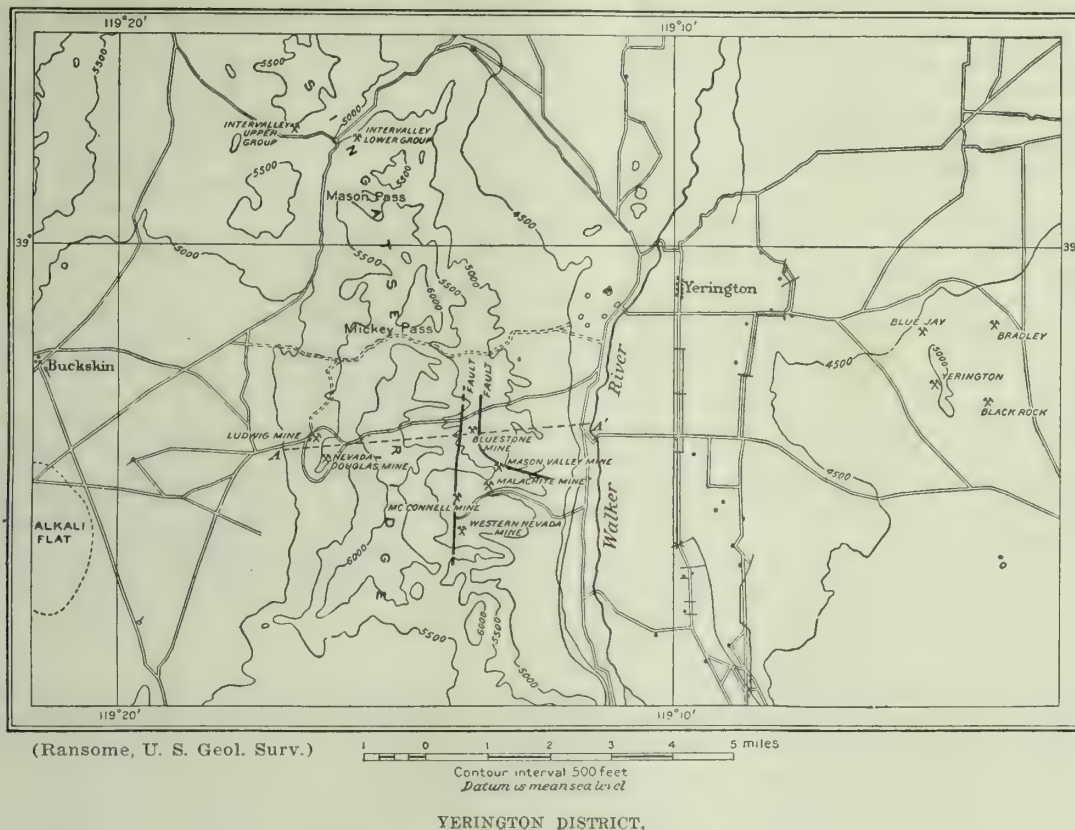

# Mines of the Yerington District

STAFF CORRESPONDENCE

The principal mines of the Yerington district are the Nevada-Douglas and the Mason Valley. Each of these mines is now shipping about 350 tons of ore per day to the smelter at Thompson, Nevada, and each expects to increase its output in the near future. These properties are comparatively well known, but there are also less prominent mines nearby which ship altogether 100 tons per day or more to the smelter, and show promise of developing into good mines with further work. A brief description of the more important of these will be of interest.

The McConnell Copper Mining Co. is shipping 60 to 75 tons per day from its mine about one mile southwest of

copper in a limestone which is in places comparatively little altered, and in others contains much garnet and epidote. Much less oxidation has here taken place. There is an adit penetrating the hillside 60 to 100 ft. below the open-cuts, and another about 70 ft. lower. Near the surface the ore contains carbonates of copper with enrichment sulphides, while the ore exposed in the lower adit consists of sulphides which are primary or due to alteration, but not to enrichment. As is characteristic of the district, the ore is extremely irregular in detail, but regular as a whole; large masses of low-grade ore have been developed, and it is not improbable that other equally large masses will be discovered. With cheap methods of mining, 3 to 4% ore can be shipped and smelted. The best way of dealing with the ore of about 2% copper content has not yet been settled. Concentration offers difficulties because of the heavy silicates present in the gangue;

the Mason Valley mine. This is an old property which produced high-grade ore some years ago, but after the rich bodies near the surface were exhausted, work on the property ceased. At one time it was under option to the Nevada-Goldfield Reduction Co., which sunk a 400-ft. shaft. Unfortunately, the shaft was started at a point where each foot in depth took it farther from the orebodies. Recently the control of the company has passed into the hands of O. H. Sonne and S. B. Elbert, and extraction of the large quantity of low-grade ore blocked out in the former workings has begun. The ore occurs in a narrow belt of limestone, which according to F. L. Ransome (Bull. 380, U. S. Geol. Survey) is bounded on the west by grano-diorite, on the east by schists, and is 300 to 400 yd. wide. There are two sets of workings, a western set, first opened many years ago, and an eastern one, across a narrow gulch, more recently driven. In both cases open-cuts have been made on the surface and adits have been driven in the hillside to cut the ore in depth. In the old workings narrow bodies of high-grade ore have been stoped; the present owners have shipped several hundred tons of 4 to 5% copper ore from the old waste dumps and are beginning to take out the low-grade ore left exposed in the old stopes. This ore is so strongly oxidized that it much resembles the soft hematites of the Lake Superior region. In the easterly workings the ore consists of carbonates and sulphides of

magnetic separation, as developed at the Bluestone mine, requires large capital expenditure to permit handling a large tonnage; leaching methods offer the same difficulties here as elsewhere, and it is doubtful whether the smelter can greatly reduce its treatment charges for low-grade ore. The present successful working is due to the use of cheap methods of mining (most of the ore being 'glory-holed' in open-cuts, and only 18 men being employed), the down-grade haul to the railroad, and the reasonable smelting rates accorded.

The Malachite, of the Yerington Malachite Copper Co., in the same gulch as the McConnell, but nearer the railroad, is immediately south of the Mason Valley on the extension of the Mason Valley orebody. O. H. Sonne is in charge and has about 10 men at work. Through an adit in the same gulch as the McConnell, 15 to 25 tons of ore per day is being shipped, while development work is being carried on at a lower level through the Mason Valley workings. I did not visit the workings, but have been told by well informed persons that the prospect of developing large orebodies in the mine is bright.

Not shown on the map, but covering the group of six small hills seen just to the west of the Walker river, near where the road from Yerington to the Nevada-Douglas mine crosses the river, is the group of 11 claims of the Empire-Nevada Copper Mining & Smelting Co. This

property is now being operated under lease by Alvin J. Smith. About 75 tons per week of 10% ore is being shipped to the smelter, the higher grade being secured by sorting.

The ore is taken from pits and shallow open-cuts scattered over the orebodies, which form hills rising above the general level of the plain because of the greater hardness of the garnetiferous limestone of the ore zones. The character of the ore of this mine is essentially similar to that of the properties mentioned. The ore at the surface has been slightly leached and almost completely converted into carbonates; sometimes cuprite is present. At a few feet in depth sulphides of enrichment occur in association with carbonates. By selective mining and sorting, considerable quantities of ore of good grade can be obtained. Probably primary sulphides will be found at inconsiderable depth, but this is not known, as the 100-ft. shaft is not in ore, though a drift is being driven to cut the ore to the east of the shaft.

East of the Walker river are several properties, of which two are shipping ore. The Yerington Copper Co. has 12 claims five miles east of Yerington. The ore here occurs in grano-diorite. There is a 400-ft. shaft on the property, and drifts have been driven at higher levels; a larger hoist and compressor are now being installed to permit more extensive work. Twenty miles southeast of Yerington is the Northern Light, where lessees are shipping small amounts of ore from surface workings.

There are a number of other properties in the district, some of which are shown on the map, which are not producing as yet. One not shown on the map, but situated north of the Bluestone, near where the road shown in dotted lines crosses the 5000-ft. contour, is the Native Copper, where work has been in progress for a few months, and some native copper is being found, together with the normal carbonates and sulphides. Mr. Ransome has summarized conditions in this district so well that his conclusion is worth quoting.

"The total quantity of oxidized ore exposed in the district is small, and there is no indication of any extensive sulphide enrichment. The quantity of gold or silver in the ores is practically negligible. The future of the mines depends on the working of low-grade primary deposits. The conditions are in some respects favorable for cheap mining and concentrating; a railroad could be constructed from Wabuska along Walker river with very little difficulty, water is more plentiful than in most other parts of Nevada, and many agricultural products can be grown in Mason valley. On the other hand, water, tailing, and smelter fume are subjects concerning which miners and farmers usually find agreement difficult."

Since then the railroad has been built, and the mining and smelting of the low-grade ores is in progress. The towns of Mason and Ludwig have developed into busy communities, and the smelter at Wabuska is working at high capacity. Smelter fume has proved a negligible question; the sulphur content of the ores is so low that all the sulphur present is required to carry the copper into the matte, and no deleterious elements, such as arsenic, are present. Concentration presents many difficulties, chief of which are the heavy silicates present in the ore, and the limited water supply, which is doubtless already fully appropriated for agricultural purposes. Leaching offers possibilities, but both sulphides and oxides are present in nearly all of the ore, and it is as yet doubtful whether any process can be developed to treat both at once.

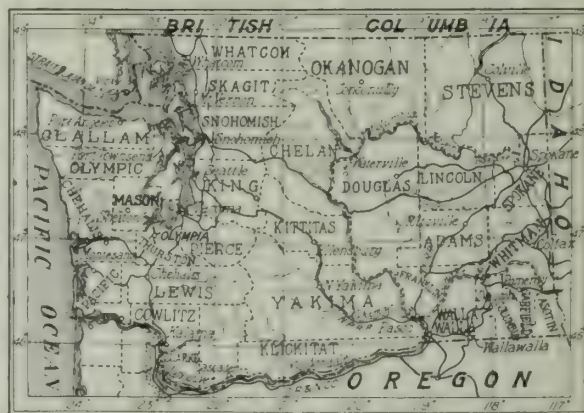

ANTIMONY ORE, according to the U. S. Geological Survey, was not produced in the United States in 1911, but considerable quantities of antimonial lead were made as a by-product in smelting precious metals, and there was a large recovery of antimony from secondary sources, such as scrap, bearing, and type metals, antimonial lead, drosses, and solder; 14,078 tons of antimonial lead containing a total of 2254 tons of antimony, valued at \$386,786, was produced.

## Tungsten Mines Near Spokane

By AN OCCASIONAL CORRESPONDENT

Tungsten mining in Stevens county, Washington, has accumulated appreciable impetus during the past two years, both east of Loon lake and in the Deer Trail district west of Chewelah. The most important deposits, or at least those upon which the greatest amount of development has been done, are in the latter district and are now owned by the American Tungsten Consolidated Corporation through recent reorganization by which it is understood control has been assumed by German capital. Development has been resumed under the management of William Scheck, who has recently returned from Germany. A recent visit to the property of the Tungsten Consolidated companies, ten miles easterly from Loon lake on the Spokane & Northern railroad and forty miles north of Spokane, permits the following description.

The formations in the district include granite, quartzite, and metamorphosed shale. The main tungsten-bearing vein is a white brittle quartz lying in the contact between quartzite and granite, with a general course slightly north of west,

MAP OF WASHINGTON.

and carrying hübnerite in large crystals which are easily and cleanly released from the enclosing quartz. Several smaller stringers, all apparently bearing northerly toward the contact, have been found in the quartzite, while in the northerly extremity of the developed area, on what is known as the Blue Grouse claim, pay-ore, which occurs in every instance in the form of hübnerite, is found in a vein of granite, with perfect cleavage separating it from the foot-wall granite and which seems to have replaced the quartz vein in which the mineral is found farther to the north. All veins and stringers dip to the southwest in degrees varying from 30 to 50.

The company's ground, which covers the entire eastern slope of Blue Grouse mountain and a considerable area on the west side, has a maximum elevation of about 4000 ft. and is capable of development by adits to a maximum vertical depth from the apex of the mountain approximately 1000 ft. It is liberally bestrewn with quartz float carrying hübnerite and ranging in thickness from a few inches to as much as three feet. The mountain is covered with deep wash and dense undergrowth, rendering surface prospecting difficult. The principal exposure of mineral in place occurs in an adit in quartzite at a vertical depth of approximately 100 ft. from the summit of the mountain. Here two stringers, from 6 to 10 in. wide, have been developed, the dump showing about 50 tons of good ore. At a farther vertical depth of 300 ft. another adit has been commenced with the object of developing the main contact vein and 400 ft. lower down the eastern slope of the mountain yet another adit has been started for the same purpose. Work has, however, been discontinued just now at both the latter points owing to lack of available funds. The lowest adit is designed as an eventual outlet for all ore

and is 110 ft. above the 60-ton mill building erected last winter and which now awaits the installation of concentrating machinery.

For the purpose of securing immediate funds the company recently leased the 5-ton experimental concentrator of the Tungsten King Mining Co. on the western slope of the mountain, and milling was commenced in July. The ore is conveyed in wagons from the upper level on the eastern slope to the ore-bins and is fed by hand to a Dodge crusher. Thence it passes automatically through 1/4-in. rolls to King screen classifiers, jigs, and two Mondell tables. By this process, necessarily more or less imperfect, the manager claims a saving of 80%. Last year ten tons of crude ore was shipped for experimental purpose to Boulder, Colorado. This showed an average of 7 1/2 tungstic acid per ton. In addition to the 60-ton mill building previously mentioned, the company has erected substantial office and domestic buildings sufficient to take care of a large staff of employees. The equipment of the new mill, designed by the Union Iron Works of Spokane, will include Blake crusher, Allis-Chalmers rolls, three King screen classifiers, 2000-lb. stamp for regrounding, three James tables, and one slimer. The underground work has been done in a substantial manner and all buildings are of excellent construction. Drift work costs about \$4 per foot. Miners' wages are \$3 per day. The ground is covered with a plentiful supply of fine timber and sufficient water has been developed, aided by a 200,000-gal. reservoir.

The manager, Mr. Brockway, is authority for the statement that the company will use the Wolfram-Neron refining process for the treatment of its mill product and that it has secured the exclusive rights for North and Central America from John C. Wichmann, now of Los Angeles and formerly refinery manager of the Wolfram Laboratorium, Berlin, in exchange for stock holdings in the Tungsten Consolidated companies. Upon some other authority, Mr. Wichmann's associates in Berlin are reported to be now making financial arrangements for the erection of the refinery equipment. The company is composed of Columbia City, Indiana, and Spokane, Washington, stockholders, with a capitalization of \$5,000,000 in dollar shares, of which 2,500,000 shares were originally held for development purposes, and about 500,000 since sold. The management is in the hands of W. A. Brockway, formerly engaged in tungsten mining in Boulder county, Colorado, and for one and a half years superintendent in that state for Philip Bauer & Co., German tungsten buyers and refiners. The company controls one and a quarter sections of patented timber lands by virtue of a bond for \$100,000, running from last year to August 1917 and entailing equal yearly payments.

# Cost of the Santa Ramona Shaft

By BENNETT R. BATES

Santa Ramona shaft, at Guadalupe y Calvo, Chihuahua, Mexico, was sunk by the Rosario Extension Syndicate, Ltd., a subsidiary to the Mexican Gold & Silver Recovery Co., Ltd., of Mexico City. It was sunk in an attempt to pierce the capping rock covering the extension of the celebrated Rosario vein. It was started March 11, 1911, and sunk to a depth of 42.30 metres with a windlass, thence driven to a depth of 131.30 metres (430.78 ft.) with a No. 1 Davis horse-whim. The bottom remains in the capping. Water was found at 42.30 metres and gave considerable trouble. At times the water hoisted equaled the waste. Sinking was stopped once for a week and two sets of timbers were placed. The timbers were 5 ft. apart and 8 by 8 in., with 6 by 8-in. centre piece. The shaft has two compartments, one 4 1/2 by 4 1/2 ft., the other 4 1/2 by 3 1/2 ft., making 8 1/2 by 4 1/2 in. inside the timbers. The shaft was closely lagged and filled in behind lagging; split-pole lagging being used. The rock was a tough rhyolite. The time consumed in sinking was ten months, two of which were lost waiting for arrival of whim held up by Revolutionists. The timber

cost \$30 per thousand. Ordinary freight cost 8c. from Parral per kilometre. Freight on the drum of the whim alone, which weighed 156 kg., cost \$120, which accounts for the high price of the whim. The wages paid were: labor-drillers, \$2 per day; shovelers, \$1.25. There was one American foreman with an American Indian helper, a part of the time, and during the remainder, the American Indian alone. The wages were \$8 and \$5, respectively, per day. The total cost was \$664.87, equivalent to \$20.11 per foot. The following costs tabulated do not include the time of the mine superintendent.

## OPERATING COSTS.

LABOR		Total.	Per metre.	
Foreman .....		\$3,005.90	\$22.89

## Mine Production in Colorado

The value of the output of gold, silver, copper, lead, and zinc recovered from placers, gold-silver bullion, and from ore sold or treated in 1911, from Colorado mines, according to Charles W. Henderson, of the U. S. Geological Survey, was \$32,418,218, as compared with \$33,673,879 in 1910, a decrease in value for 1911 of \$1,255,661. These figures are compiled and tabulated strictly as a mine report and with reference to the locality of each individual mine, and not with reference to the locality of the shipping point of the product. The production of gold showed a decrease in value of \$1,505,083; the output of silver one of \$710,194 in value; the production of copper, another of \$58,600 in value; and the production of lead, a similar decrease of \$211,568 in value. The output of zinc (figured as spelter and zinc in zinc oxide) showed an increase of \$1,229,784 in value. Details are given in the table below.

Cripple Creek supplied 56% of the total gold yield of the

of the total output, San Miguel and Gilpin each 12%, and the six counties combined, 95%. While copper in Colorado is of subordinate importance to gold, silver, lead, and zinc, the total recovered copper from Colorado ores in 1911 had a gross value of \$1,003,061.

There was a material decrease in the output of lead in 1911. Large decreases in output were made in San Juan, Pitkin, San Miguel, Park, Lake, Mineral, and Hinsdale counties. Increases of note were made in Clear Lake, Dolores, Eagle, Gilpin, and Summit counties. Lake county ranked first, and was followed by Pitkin, Mineral, San Juan, San Miguel, and Summit counties, in the order named.

Of the Colorado zinc output of 94,607,456 lb., Lake county yielded 76%, with an increase in output for the year of 15,243,011 lb. Leadville zinc carbonate shipments, which were only 8059 tons in 1910, amounted to 83,905 tons in 1911, while the tonnage of zinc sulphide ore decreased from 163,218 tons to 79,981 tons. Increased production of zinc was also made in Clear Creek, Dolores, Eagle, Gunnison, San Miguel, and Summit counties. Heavy

### MINE PRODUCTION OF GOLD, SILVER, COPPER, LEAD, AND ZINC IN COLORADO IN 1911, BY COUNTIES

<sup>a</sup> Includes placer production.

state, with an output of \$10,562,653, as compared with \$11,002,253 in 1910. Conditions in the Cripple Creek district were much the same in 1911 as in 1910, for the subsidence of water through the Roosevelt tunnel was so slow that it was not possible to increase operations. At the close of the year, after the tunnel had been driven farther, the water drained more rapidly. The gold yield from the San Juan region fell off considerably, San Juan and Ouray counties contributing chiefly to the decrease. Counties showing an increased output of gold were Boulder, Costilla, Gilpin, and Mineral. The placer output of gold was \$319,759, a decrease of \$75,706 from the output for 1910.

Leadville (Lake county) continued to be the chief silver district, with an output of 3,007,296 oz., which represents 41% of the state yield. There were notable decreases in production of silver in La Plata, Mineral, San Juan, and San Miguel counties. Notable increases in output of silver were shown in Eagle, Gilpin, Ouray, and Summit counties. The chief silver-producing counties in Colorado in 1911 were Lake, San Miguel, Mineral, Ouray, Pitkin, Clear Creek, San Juan, and Gilpin, in the order named; these counties combined furnished 90% of the total state production.

Copper production was reported from 21 counties in 1911, and of these, Lake, San Miguel, Gilpin, Clear Creek, Ouray, and San Juan counties, in the order named, were the most important producers, Lake county alone furnishing 50%

decreases were made in Mineral and San Juan counties, and appreciable decreases were made in Chaffee and Park counties. Zinc in concentrates in 1911 amounted to 41,262,830 lb.; in crude ore, 53,344,626 lb. In 1910 zinc from concentrates was three times that from crude ore.

The number of deep mines producing metals in 1911 was 861, against 856 in 1910. The average total recoverable value per ton of ore produced decreased from \$13.67 in 1910 to \$13.59 in 1911.

There were 2,377,936 short tons of crude ore from Colorado sold or treated in 1911, a decrease of 56,728 tons from the output of 1910. Of this total, 1,373,879 short tons went to gold and silver mills, 465,283 tons went to mills for concentration only, and 538,774 tons went crude to smelters.

SILVER production in Montana in 1911 was 11,985,196 fine ounces, against 12,162,857 oz. in 1910, according to the U. S. Geological Survey. In the silver output of the United States, Nevada takes the leading place, which Montana held in 1909 and 1908. Eighty per cent of the silver output of Montana came from copper ores and nearly 14% from silicious ores. Bullion at gold and silver mills produced only 122,823 oz., concentrate 7,751,426 oz., and crude ore shipped to smelters 4,105,092 oz. Silverbow county furnished 85.5% of the state's production. There were 430 deep mines producing metals in Montana in 1911, as against 423 in 1910.

## Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

### A Unique Scheme of Elevation

The Editor:

Sir—I had occasion to observe a method of handling some rather low-grade gravel recently in northern California which rather impressed me by its simplicity. The mine is on Grouse creek, in Trinity county, and it had been run at a loss before the present owners operated it.

The method of operation is shown in the attached drawing. The sluice-boxes are laid along the side of the hill, some distance above the creek bedrock. Enough space has

ELEVATING TO HILLSIDE SLUICE.

been gained in the creek to dump tailing, and self-drainage had been established. As the tailing runs from the end of the sluices the drain is continually covered over, to prevent it from filling up. The gravel is worked crosswise, from bedrock, and driven up an incline to the head of the boxes. Of course, local topographical features have a good deal to do with the choice of method, and if the slope was too steep or the gravel too deep, it would be impossible to work in this manner.

C. S. HALEY.

Newark, California, July 15.

### Alaska Problems

The Editor:

Sir—I regret to observe that the *Mining and Scientific Press* is becoming more loyal to the Roosevelt-Pinchot system of unbridled bureaucracy than it is to those who find mineral, and develop mines. Here in Alaska we have borne the burden of this un-American bureaucracy until we have become galled and raw. I do not believe you have been subsidized. I believe you are honest, but I submit that when you advocate a policy which places

the public domain and natural resources in the hands of a bureau to become the spoils of bureaucracy, that you are promoting bureaucracy at the expense of the industry named in your title. I am willing to concede that there is sometimes an honest difference between the views of the theorist and the victim. But, if we are to continue finding and digging ore in the face of bureaucratic hindrance which you indorse and encourage, then you will serve the industry chiefly as an illustration that the pick is more potent than the pen in winning the minerals of the earth for the use and benefit of mankind.

U. S. RUSH.

Kasaan, Alaska, July 24.

[We value the good opinion of our friends in Alaska highly, and while it is too much to expect at present complete agreement as to plans, we are at least one in purposes. We have advocated strongly the bill for railroad construction in Alaska framed by the Alaska Committee of the American Mining Congress, and we have favored a leasing system as applied to the coal lands, not only as correct in principle but as the only solution of present difficulties that commands enough public support to raise reasonable expectation of its being enacted into law. It may be noticed that the Governor of Alaska and many other Alaskans have come to occupy the same position. We admit, sadly, the danger of bureaucracy incident to the leasing system, but we believe that a properly framed leasing law will minimize this danger, and from long and personal acquaintance with men in the Government service, we have an unhesitating belief in the possibility of securing in Alaska as honest and efficient enforcement of law as, for example, in the Canal Zone. Incidentally, we would call attention to the fact that under any leasing system there could not be less coal mined in Alaska than now. It may also interest our correspondent to know that but a few days before his letter came we received another from a valued friend protesting with equal energy that we were unfair to Mr. Roosevelt and calling attention to the fact that many, or as he thought "most", of our readers are Roosevelt partisans.—EDITOR.]

### Tin at Grants Pass

The Editor:

Sir—in the interest of the mining development in southern Oregon, I feel constrained to write you concerning the alleged presence of some of the less common metals, such as tin, tungsten, and platinum.

In January 1911 T. A. Rickard wrote a letter to the Southern Oregon and Northern California Mining Congress which convened at Ashland, asking that steps be taken by said congress to verify or deny the reports continually coming from the vicinity of Grants Pass with reference to the tin question. A few weeks later the Commercial Club of Grants Pass officially requested the State Bureau of Mines to make investigation of the same. This request was again repeated at the meeting of the Oregon Mining Congress at Portland in May 1911. In response to these requests, the Bureau of Mines took it upon itself to make a brief preliminary investigation. Accordingly, in the latter part of June 1911, Mr. Swartley, my assistant, and myself proceeded to Grants Pass and first interviewed some of the prominent citizens of that city, asking them to cite us to the parties who claimed to have the high tin values. We visited four different properties which were claiming the highest amounts of tin, and took samples ourselves of what was claimed to be the highest grade tin ores. These samples we brought to the laboratories at Corvallis and made a very careful investigation, both mineralogically and chemically. Our report was made at the Mining Congress held at Grants Pass July 5, 6, and 7, 1911, and was to the effect "that while it would be unscientific to state that there is no tin in the district, we, however, found no tin in the samples which we procured from these alleged tin properties." We found also, that some of the minerals claimed to be tin minerals were tourmaline, horn-

blende, magnetite, and chromite. We also found, while in the Grants Pass vicinity, that the tin reports originated with certain assayers in Grants Pass, who in order to make business good, appeared to give out promiscuously, encouraging reports in which tin was given in very generous quantities; platinum was reported in large percentages from base ores, as well as tungsten.

We had supposed that our verbal report given at the Mining Congress at Grants Pass would be sufficient to convince the truth-seeking public. However, since that time, we have found that there are certain parties in the Grants Pass vicinity who have been doing all in their power to discredit our report, and since I have noted from time to time certain articles in your periodical with reference to certain development work that is being pushed by some of these tin, platinum, tungsten (?) properties, it has seemed to me that in order to further the interest of the mining development in southern Oregon, we should make the foregoing statement, both for your information and for publication.

H. M. PARKS.

State Bureau of Mines, Corvallis, Oregon, July 29.

[We are grateful to Mr. Parks for his letter. Such examinations as he has made lie in, we believe, one of the most useful fields for state geological surveys and mining bureaus. News of development and of reported discoveries from many districts comes in regularly, and as Mr. Parks says, it would be unscientific to deny them without specific evidence. For that very reason it is all the more important to have such information as contained in his report, periodically reprinted.—EDITOR.]

### Research in the Mining School

The Editor:

Sir—According to a recent editorial in the *Mining and Scientific Press*, mining schools, as a whole, need galvanizing into activity in the matter of research. This is especially true as regards the departments of metallurgy. I have in mind two of the leading mining schools in the western part of the United States, where, for the past ten years, as far as I am able to ascertain, nothing in the nature of research has been published. In these cases, the duty to the state which supports them has not been fulfilled—for two reasons: (1) they are not doing the research which should be done by institutions supported by the government; (2) the instructors are not giving the best that is in them in the way of instruction; for no one will deny that if a man uses his mind to a certain extent for original work he will be much better fitted to train the student to grapple with the practical problems to be met with later in his professional activities.

The reasons that more research is not done are several: (1) lack of time; (2) lack of inclination; (3) lack of money; (4) lack of encouragement from the powers that be; (5) lack of ability. Of these, lack of inclination and ability are the most valid, though the others are always given. If the administration forbids research, there is no remedy except a new administration, which is, as a rule, out of the reach of the instructor. He can, however, change his location. Lack of time, lack of help, and monetary considerations can be remedied in most cases by the man himself, provided he possesses the inclination and ability for the research. Interesting minded people outside the institution, is a comparatively simple matter for the right man.

We need more original investigation—not the testing of an ore new to the experimenter, by several old 'cut and dried' processes, but the devising of new and original processes and research. The instructor doing such work will be a better man himself. He will be worth more to the student, to the institution, and to the public at large. Any school administration would do well to require a certain amount of productive research from the instructors. For it will be found to be true, almost without exception, that the technical schools which have the best reputation and

whose diplomas are 'worth the most' are those at which the most research is conducted.

R. C. BENNER.

Pittsburg, July 24.

### Nevada Consolidated Copper Company

During the quarter ended June 30, the mill of the above company treated 813,141 tons of ore averaging 1.66% copper. Of this, 731,299 tons was from the open pits, and 81,842 tons from the Veteran mine. The production of copper amounted to 18,092,439 lb., against 17,578,450 lb. for the first quarter of the year. The Steptoe plant milled 26,924 tons of ore for the Giroux Consolidated Mines Co. during June, but the copper from this ore is not included in the above yield. Development work to prove the existence of ore at depth in the Eureka pit will be carried on in August and September, when conditions in the bottom of the pit will be favorable for deep drilling. The work will have then been carried farther west, and will give a larger area for drilling below the bottom of development holes.

The profit and loss account shows the following for the past quarter:

Earnings from mines, investment, and miscellaneous .....	\$1,628,859
Dividend No. 11 .....	749,784
Net surplus for quarter.....	\$ 879,075
Less depreciation for Steptoe plant...\$141,160	
Less ore extinguishment .....	134,603
	275,764
Net credit to undivided profits.....	\$ 603,311

Production by months has been: Jan., 6,309,228 lb.; Feb., 4,888,790; March, 6,380,432; April, 6,115,095; May, 6,063,462; June, 5,913,882. The quantity and value of copper in transit materially increased, as did also the copper on hand at the Steptoe plant. The total increase in value of metals on hand was \$702,611.

### Tin Shipments and Prices

According to L. Vogelstein & Co., domestic deliveries of tin for the month of July are estimated by the Metal Exchange at 5150 tons. The average consumption for the first seven months of the year is 4000 tons per month. If this rate is maintained for the year a new high record will be established, the largest deliveries heretofore being 45,350 tons in 1910. The increase to date over last year is 3400 tons. These figures include Atlantic ports only. European deliveries are small, due to strikes abroad and the lateness of the Banca sale on July 31. The total London, Holland, and Continental deliveries in July were about 3000 tons, and the average for the first seven months is 3500 tons per month. The total foreign and domestic deliveries for the year to date show an increase of 6800 tons over the preceding year.

Straits shipments show an increase of 3200 tons for seven months, but Bolivian shipments, and those from Australia show a slight falling off, and arrivals of non-statistical brands in the United States are also smaller than last year. Hence there is a decrease of 3000 tons in the visible supply on July 31, as compared with December 31.

The outlook for a future increase in supplies is not encouraging. Even the Straits have exported 1800 tons more than was produced and imported into the district. The Dutch Government has announced that Banca sales will be reduced to 1500 tons per annum. This was necessary, as sales were in excess of production. July closed with 1339 tons on hand and about as much afloat to arrive in August. The large consumption of the United States will compel this country to draw freely from foreign reserves, where stocks are already depleted. The situation is strong, and a continuation of high prices expected.

## Special Correspondence

### NEW YORK

CONSOLIDATION OF MINING COMPANIES.—FORMATION OF ALASKA GOLD MINES CO.—PRODUCTION OF TUOLUMNE COPPER CO. A DISAPPOINTMENT.

The market in copper metal has been unusually quiet. The buyers and selling agencies alike seem, for the moment, inclined to mark time. There are many reasons for believing that a much larger movement may be seen within the next 60 to 90 days, but the situation will hardly right itself until the producers see fit to show their hand in regard to the blister copper piled up in the yards of the various smelting plants. Some of the large copper producers are evidently looking forward to an increased demand, and are planning some interesting deals. The Phelps-Dodge company is negotiating for the property of the Chemung Copper Co., in Grant county, New Mexico. This latter company is controlled by a group of Pittsburg capitalists. John K. Tener, Governor of Pennsylvania, is president of the company, and 'Cap'n Jim' Hoatson is one of the directors. The company is a reorganization of the old Tyrone Development Co. and owns 55 claims in the Burro Mountain district near Silver City, New Mexico. The company's stockholders are to meet in Duluth, Minnesota, on August 15, to act upon the offer made by the Phelps-Dodge people, which is said to be \$1,350,000 cash for the property. The purchase of the properties partly developed by the Chemung Copper Co. is illustrative of the hold which the various groups of copper producers, now working in harmony, have over the whole situation. The management of the Chemung company has expended some \$2,000,000 in development of its ground, in the hope that it would be able to secure some degree of co-operation from adjoining properties, and so be enabled to extract its ore at a profit. The company's funds have been exhausted, and the orebodies as now developed are not large enough to justify borrowing funds or the erection of an independent reduction plant. There are not many copper properties now partly developed to which this state of facts does not apply to some extent. Copper production is becoming essentially an operation in which only very large capital with experienced engineers can be employed profitably. The individual as an individual is practically eliminated from all opportunity of making money out of copper production.

The recent statement prepared by J. F. Callbreath, secretary of the American Mining Congress, and laid before the U. S. Senators and Members of the House of Representatives, is in part along these lines: Mr. Callbreath makes particular mention of the fact that the number of men employed in mining, milling, and smelting in Colorado decreased more than one-half during the period from 1900 to 1910. Speaking of the effect upon the industry of the employment of large organizations, Mr. Callbreath says in part: "A solution of the problem of economical treatment of low-grade ores is the one method through which this great fundamental industry can be revived. This problem is too great for private enterprise, and whenever improvements are made by private effort the results are kept secret and do not serve the general good. The West has a right to expect Federal aid in the solution of these problems." "It has always been the boast of the mining industry that primarily it depended upon the individual—the prospector with his burro, shovel, pick and hammer, and tiny camp outfit—and the elimination of the individual is very apt to be followed by just the state of affairs reported by Mr. Callbreath. In the development of natural resources it is the individual that must be encouraged.

The Guggenheim interests are said to be in negotiation for the property owned by the Lake Superior & Arizona Mining & Smelting Co., which consists of 17 claims, 30 miles west of Globe, Arizona. The property has produced

a small quantity of copper with a little silver and gold, but was idle from 1907 to 1910, when the development of the property was undertaken by the Magma Copper Co., which at that time took a bond and lease on the Lake Superior & Arizona ground. The present control is said to contemplate development by the Guggenheim people on a basis of payment of \$400,000 cash and 40% of the stock of the company to be organized to hold and develop the mine; or to acquire the property by the payment of \$800,000 in cash at the end of one year, or \$1,000,000 in cash at the end of two years.

The general attitude of the public toward precious-metal mining has always justified the maxim that it is impossible to make a boom camp without high-grade ore. The general public loves the spectacular in mining. The excitement and the romance that made history in so many spots on both slopes of the Rocky Mountains was in nearly every case due to rich ore. Some of the older countries on the other side of the water have long ago outgrown this feeling, and have come to prefer low-grade properties of large known orebodies. Education in this direction is making progress in Eastern financial centres. Hayden,

MINE AND MILL OF THE ALASKA PERSEVERANCE.

Stone & Co., who have long been identified with the financing of the Guggenheim porphyries, have for some time been making search for a low-grade gold-mining property, and have just recently secured a group of claims lying next to the Alaska Juneau ground at Juneau, Alaska, known as the Alaska Gastineau property. The present organization is a consolidation of three groups of mines, known as the Alaska Perseverance, which has figured in three or four deals during the past five years; the Oxford and the Sheep Creek. The present company has a capitalization of \$12,000,000 in stock, and \$3,500,000 in bonds. D. C. Jackling, head of the Guggenheim management, together with A. F. Holden, are just returning from an examination of the property. Contemplated operations will be on a very large scale, and will involve an outlay of some \$5,000,000 in the erection of a 6000-ton mill with a cyanide plant. The 80% interest which Hayden-Stone have under option is to be placed in the treasury of a holding company, to be known as the Alaska Gold Mines Co., the stock of which latter company will, in accordance with the usual custom of Hayden-Stone, be offered to their clients. At present the engineers estimate the property to have an earning power of \$1,500,000 per year.

The action of the Tuolumne Copper Co. has been most disappointing to Eastern shareholders, most of whom have waited for three years through the earlier stages of development and equipment, and then through a dull copper market, to see the mine fully equipped with a big Nordberg hoist, and copper at better than 17½¢, only to be confronted with a monthly output of less than three-quarters of a million pounds. Tuolumne's output for July was 605,000 lb. of copper, made from 7500 tons of ore. The company has a new smelting contract covering the treatment of its second-class ore, of which a large tonnage has been developed, and it is said this can now be mined at a good profit.

Two suits have been filed against the United Copper Co.

praying for a receiver for the Heinze concern. One by Paine-Webber of Boston and one by T. H. Ball of Philadelphia. There is apparently some little activity in mining ground in Butte adjoining the Butte & Superior. The Butte & Superior management has obtained options on some claims, and it is expected that a new company will be formed and the shareholders given the opportunity to subscribe, provided they ratify the plan of acquiring the ground.

The International Smelting & Refining Co. is eventually to make a bid for a large share of the business of lead refining. A fifth furnace is to be added to the plant at Tooele, Utah, and it is stated that there is a sufficient amount of lead ore under contract to keep the four 400-ton furnaces in steady blast. The East Chicago plant of the International company is going up as rapidly as possible; the steel work is nearly all in and it is expected that the first furnace will be blown in in October. It is understood that the International Smelting & Refining Co. has some important development in the way of new reduction processes, details of which are not as yet obtainable.

So far as the Eastern market is concerned, interest is in large part centred in the Tonopah district. The activities of the various properties at Tonopah are closely followed and such market activities as prevails is mostly in these stocks. Montana-Tonopah is spreading out to build a mill for the Common Wealth property at Pearce, Arizona, which it recently acquired. Tonopah Merger continues to be active, and the market interest, which for some time was centred altogether in Tonopah Mining and Belmont, is spreading to other properties in the district as having large possibilities.

## BOSTON

COPPER SHARES NEARING TOP PRICES.—BROKERAGE HOUSES

INSPECT MINING PROPERTIES.—CANADIAN INTEREST IN AMERICAN MINES.

The progress of the copper market has not entirely stopped with the summer heat. There is a feeling in Boston that a price of 20c. per pound may be reached for the metal before the end of the year, and with this hoped for advance is expected a better distribution of copper shares to the public. It is noteworthy, however, that a number of Boston coppers have been already pushed to the level of their highest prices in the last three years. Some others which have not reached the price paid in the speculative boom in 1909 are within a few points of that mark.

William F. Bartholomew, of Thompson, Towle & Co., and George L. Walker, editor of the *Boston Commercial* and *Walker's Weekly Copper Letter*, have been recently visiting in the Lake Superior copper district. Both of these men are very optimistic over the bumper crops in the Northwest, the copper situation in the Lake country, and the prospects of record business. Mr. Walker believes that the lodes of the Calumet district will be profitably operated for hundreds of years. It is becoming customary for members of brokerage houses specializing in copper to visit the mining districts periodically. The broker has a different viewpoint from a mining superintendent or engineer, and even where he has full access to their reports he wants to see conditions for himself. The Chicago, Milwaukee & St. Paul railroad has been advertising in the Boston papers its special service to the "copper country," Lake Superior. Interest is not confined to this district, however, and Boston is watching Butte, and the Arizona, Utah, and Nevada districts with equal eagerness. A bid of \$1000 per share for stock of the old Standard Oil Co. of New York, reminds brokers of the time when Calumet & Hecla sold at exactly \$1000, which is believed to be a record for the stock of a mining company. Some Canadian capitalists are now becoming interested in American mining. It was recently announced that Frank Armstrong had acquired control of La Rose. Mr. Armstrong is himself interested in Cobalt, and his business associate, D. Lorne McGibben is president of La Rose. In the Butte, such Canadian bankers as Sir Henry

M. Pellatt; Sir Frederick W. Borden, and Sir Rodolphe Forget, of Montréal, are heavily interested in Butte Central, which company is now building a mill. American capital has led in building up the mining industries of Ontario and British Columbia, and it is a good sign when financiers of Canada reciprocate by assisting in the development of properties in established districts such as Ely and Butte.

## BUTTE, MONTANA

SETTLEMENT OF WAGE QUESTION AT SMELTERS.—MINING

CLAIMS IN DEMAND.—HOISTING OF ORE RESUMED IN THE ANACONDA SHAFT.

The smeltermen of Anaconda and Great Falls have accepted the offer of the Anaconda company of an increase of 25c. per day in wages. This is a compromise. Some time ago the Great Falls smeltermen's union decided to ask for an increase of 50c. per day, and afterward the smeltermen's union of Anaconda joined with the Great Falls men in the demand for the increase. When the question came before the officials of the company, through a committee, the wage question was thoroughly discussed, and in due time the company gave an answer declining to accede to the request, but offering an increase of 25c. per day so long as copper remained at 15c. per pound or over. The two unions referred the offer to a referendum vote of the members, and they accepted. The condition of the offer was that a contract should be signed for at least three years, to date from July 1. Final figures of the U. S. Geological Survey credit Montana with a production of 272,847,705 lb. copper in 1911. All but 589,253 lb. of this came from Butte.

Mining claims which have been regarded as next to worthless for several years in the northern part of the Butte district, are bringing high prices. The Ready Cash claim, which a year ago could have been secured for \$10,000 or even less, recently changed hands for \$110,000, there having been \$10,000 paid in cash with an agreement to pay the rest in a year. The Narragansett, which was sold a few years ago for \$2.64 at sheriff's sale, to satisfy delinquent taxes, is now under option for \$75,000, while there are several other instances of claims selling all the way from \$80,000 to \$135,000 which a few years ago could have been secured for the payment of the taxes. This boom was started by A. B. Wolvin, president of the Butte & Superior Copper Co., and John M. Hayes of the Utah Copper Co. purchasing claims adjoining the Butte & Superior property. Then Duluth people secured options, and the fever to secure claims spread. Prominent among the people who are buying up claims is Chester Congdon, and he is said to have associated with him Thomas F. Cole. Mr. Cole and his associates have six claims just east of the North Butte and north of the North Butte Extension, and have options on other claims in the vicinity, although no record has yet been made of an agreement for a sale. Bruce McKelvie of Hayden, Stone & Co. is said to be carrying on negotiations of some kind for the financing of the Butte & London Copper Development Co. There is also a report that an effort is being made to finance the Butte & Bacon M. Co. and resume development. When work was stopped on this property it was said that the prospects of opening up good orebodies were excellent, but lack of money and unfavorable market conditions compelled the closing of the mine. Henry Turrish, of Duluth, has secured options on eleven claims in the northern part of the district through John McBarren, who has held them under option for years. The claims assigned to Mr. Turrish are known as the Blane, Copper King, Washington, Peoria, Robert Emmet, Sarah Alice, William J. Bryan, Rising Sun, Arctic, Sundae, and Christie. In the struggle for mining claims the courts will reap some benefit, as two options on one piece of property have been given, one to Arthur V. Corry, representing A. B. Wolvin and John M. Hayes, and the other to Eugene B. Milburn, who represents the Cole-Congdon syndicate.

The Anaconda shaft has been used for hoisting since

August 1, for the first time in four years. During this time the fire in the orebody has been completely enclosed by cement bulkheads, the workings put in good order, and the shaft completely retimbered. B. B. Thayer, president of the Anaconda company, after being in the city for the past six weeks inspecting the various properties of the company, has completed his work and left for a short visit in California. Mr. Thayer not only made an inspection of the mines of this district, but he also made an examination of the Washoe smelter and the plant at Great Falls, together with the lumber properties in different parts of the state. The mines were found to be in first-class condition and capable of responding to any emergency. Some improvements are being made to the smelter at Anaconda which will be completed about the middle of the month, and this will mean that the Washoe will have an increased capacity. Mr. Thayer regards the copper situation as highly satisfactory, and says that sales now being made are for October delivery.

Directors of the Tuolumne Copper Co. are not disposed to tell when dividends will be resumed. The greater portion of the ore going to the smelter is second class, and with copper around  $17\frac{3}{4}$ c. per pound, it is a good time to get clear of the large amount which has been allowed to accumulate for the past two years. It is stated that in the course of two or three weeks the shipping of first-class ore will be resumed in larger quantities than at present.

### SALT LAKE CITY, UTAH

JULY PRODUCTION OF COPPER COMPANIES.—ENLARGED LEAD SMELTER PLANNED BY INTERNATIONAL S. & R. CO.—AMERICAN S. & R. CO. MAY MOVE MURRAY PLANT.

The month of July will show record production for the Utah Copper Co., Ray Con. Copper Co., and Chino Copper Co., according to D. C. Jackling, general manager for the companies. Mr. Jackling claims that before long the Utah property will be producing at the rate of 150,000,000 lb. of copper per year. The Chino, he says, treated on an average of 3000 tons per day, and Ray Con. 4500 tons per day during the month. The complete official figures on all these properties will be forthcoming later. Mr. Jackling and A. F. Holden, managing director of the United States Smelting, Refining & Mining Co. have returned from a trip to Alaska, where they went to inspect the Alaska Perseverance and adjoining properties held under option by Hayden, Stone & Co. If the option is exercised as a result of this examination, it is understood that both the Guggenheim and the United States mining interests will have a hand in the operations. The Perseverance is a neighbor of the Treadwell, and now has a 100-stamp mill in operation, which works only four or five months a year, when the streams which furnish the water supply are not frozen.

The plant of the International Smelting & Refining Co. at Tooele was built primarily as a copper smelter, but the treatment of lead ores has assumed greater importance. The production of the Utah Consolidated Copper Co. has fallen off, and the supply of ore from other sources has not been all that was anticipated. On the other hand, the strength of lead and the establishment of favorable smelting and railroad rates for low-grade ores have combined to stimulate lead production, so that the receipts of lead ore exceed the present capacity of the lead furnaces. The Prince Consolidated of Pioche now has railroad facilities and is shipping a good tonnage regularly, while other new contracts have either been signed or are being negotiated. Three furnaces are already in operation, and a fourth has been ordered. Following a visit to the plant in company with Dennis Sheedy, of Denver, vice-president, E. P. Mathewson, general manager for the company, announced that the directors had been requested to make an appropriation for two additional furnaces. This will make a total of six, with a daily capacity of 1500 tons. The American Smelting & Refining Co. is reported to be contemplating

moving its Murray plant into a location where the town and the entire surrounding territory can be directly controlled by the company, as is the case at Garfield. In fact, if the move is made, it is altogether likely that the lead smelter will be erected close to the copper smelter at Garfield. The Murray smelter is now directly in the town, which is independent, and close to a large number of farms whose owners are constantly claiming damages on account of smoke. Before the Garfield copper smelter was started, the company purchased the land for miles around, and fortified itself still further by taking photographs of all farms for a still greater distance, so as to be ready with evidence in case suits were started for ruining formerly valuable

SHAFT OF PRINCE CONSOLIDATED.

farms by smoke and fumes. As a result, the 'smoke farming' industry has not thrived so well around Garfield as it has around Murray. The company also owns and controls entirely the town of Garfield.

### JOHANNESBURG, TRANSVAAL

FAILURE OF THE WAY-ARBUCKLE PROCESS.—DISCUSSION AT ANNUAL MEETING OF THE BENONI CONSOLIDATED MINES COMPANY.

The principal mining topic of interest here is the failure of the Way-Arbuckle process at the Benoni Consolidated Mines. The details of this process were published in the *Mining and Scientific Press* of May 25, and the failure predicted. During the week the annual meeting of the Benoni Consolidated has been held, and as the result of disclosures made at this meeting the failure of the Way-Arbuckle process has been brought to the front. The Benoni mines are owned by the Anglo-French Exploration Co., Farrar Brothers, and the Jumpers company. The Anglo-French company supplies the consulting engineer, E. J. Way, and the Jumpers company the mine manager. This involves a dual management from the start. The Benoni Consolidated had £280,000 in cash available to buy a neighboring property, and to develop and equip the mine. After carrying out this work the company had an actual cash deficit of £195,000, a fairly well developed mine, but only half an effective equipment. When it came to equipping the mine the directors found themselves short of working capital and with a heavy loan from the bankers staring them in the face. The Way-Arbuckle process was recommended by the consulting engineer on the grounds that its secondary treatment would involve a saving of £31,000 in the first cost, would treat the sand and slime in as many hours as the ordinary treatment required days, while giving a very high and satisfactory extraction; features of importance to the Benoni company. All these promises have, however, proved delusions. At the outset troubles arose in connection with the Arbuckle screw elevators belonging to the de-watering and de-solutionizing

cones, and they were replaced by ordinary centrifugal pumps. The centrifugal pumps failed to remove the settled slime as anticipated, and the process at once became an intermittent rather than a continuous process. The next trouble arose with the Brown treatment-tanks, owing to a sufficient and uniform supply of air not being available, with the result that the slime was discarded and thrown aside for future treatment, and a larger tonnage of sand put through the tanks in the hope of making up for the loss of the slime. Still the process was intermittent, as, on the slightest stoppage of the air or power supply, the agitating-tanks immediately silted up, involving much loss in cleaning out and restoring them to working order. The operating costs were also found to be abnormally high, and after working several months in an intermittent and experimental manner without profits or prospects of success, although the screen values were consistently satisfactory, it was decided to close down the plant rather than go on exhausting the ore reserves without any prospects of making profits to reduce the company's liabilities. Laurie Hamilton was called in by the Jumpers company to report on the mine. He confirmed the action of the directors in closing down the plant. F. L. Bosqui was also consulted. He advised that, as the plant stood, the cyanide portion could not possibly be operated in a successful manner, and recommended wholesale additions and alterations, which the company did not in its financial condition see its way to make. Since then consolidation with the adjoining Apex property has been proposed and considered, but at the time of the meeting negotiations had failed. At the meeting of the shareholders held the other day the consulting engineer was severely called to task by the representatives of the Jumpers mine for his recommendation to the board of the installation of a worthless method of treatment, and for his inability to work the plant to advantage although it was left entirely in his hands. The consulting engineer, in reply, blamed the mine manager, the reduction employees, and the patentee for failing to render the necessary assistance in the matter. They in turn all deny any responsibility, owing to the consulting engineer taking the whole control into his own hands. Here the matter rests, the mine standing with a liability of £200,000 and those interested having such conflicting views that it is difficult to see the result. Perhaps by co-operation the mine may be put on its feet, but it will be some time before the shareholders regain the losses caused by the introduction of the Way-Arbuckle process.

### LONDON

OPERATION OF RUSSIAN COPPER COMPANY.—ORGANIZATION OF SUBSIDIARIES TO THE NORTHERN COPPER (B. S. A.) CO., LTD.—OPERATION OF COMPANY IN RHODESIA.

The Kyshtim group of copper producers in Russia is of special interest in America, for the mining and metallurgical work has been largely in the hands of Americans. R. Gilman Brown is consulting engineer, H. W. Turner geologist, E. J. Carlyle and W. G. Perkins metallurgists, while H. C. Hoover and A. Chester Beatty had a hand in providing capital. A review of the recent operations will therefore be of interest. The English company was formed in October 1908 to acquire the share capital of the Kyshtim Mining Works Co., the Russian company which owns and operates copper, iron, and gold mines in the Perm district of the southern Urals. In addition, the company has made loans to the Russian company amounting to £761,152, for the purpose of reorganizing the mining and metallurgical work at the copper mines. The capital is £1,000,000 in ordinary shares, and there are £650,000 debentures. During 1911, 247,102 long tons of ore was raised from the Koniukhoff, Smirnoff, and Tissoff mines, averaging 3.19% copper. The amount of ore treated at the new smelting plant at Karabash was 218,310 tons, and at this plant and at the old Kyshtim works, where matte, flue-dust, etc., are still treated, the total production of blister copper during the

year was 5020 tons. At the electrolytic refinery, 4033 tons of copper was produced, together with gold and silver slime that sold for £55,321 or £13 14s. per ton of copper. The cost of operations, including mining, smelting, transport, and general expenses, was 15s. per ton of ore or £34 per ton of blister copper. The reserves as estimated by R. Gilman Brown in June of this year amounted to 1,699,000 tons averaging 3% copper, 2 dwt. gold, and 1 oz. silver per ton. At the Karabash smelter, a third blast-furnace was started in May of this year. The dust-chambers have been enlarged, and the main chimney heightened by 60 ft. A second reverberatory has been started at the Kyshtim works to treat the flue-dust and fine ore. It is probable that the output of copper during 1912 will be of 7000 to 7500 tons. The Russian company made a profit of £172,391 on the copper production, £23,439 at the iron works, £29,651 in the timber business, and £4919 from the sale of pyrite for sulphuric acid manufacture. The general expenses, taxes, and interest on mortgages and bankers loans absorbed £119,135, and £30,033 was written off for bad debts, while £65,200 was remitted to the English company. Out of the latter, £23,657 has been paid as debenture interest, £9289 was paid as directors' fees and London expenses, and other amounts debited for formation expenses and discount on new debentures, etc.

Besides the Tanganyika Concessions, there are other companies operating copper mines in tropical Africa. One group is that of the Northern Copper (B. S. A.) Co., Ltd., that was formed in 1895 to acquire prospecting and mining rights in northwest Rhodesia. Percy Tarbutt & Co. are the consulting engineers. Almost all the properties so far developed are old native workings. In 1902 a number of the properties were handed over to a subsidiary, the Rhodesia Copper Co., which in turn, acting in concert with the parent company, floated three separate organizations, namely, the Rhodesia Broken Hill, the Kafue Copper, and the Bwana M'Kubwa Copper. The Rhodesia Copper Co. also has a financial interest in the Rhodesia-Katanga Railway & Mineral Co., which is under the control of the Tanganyika Concessions and owns the Kansanshi copper mine. Northern Copper still holds 363,000 shares in the above-named companies, valued at £116,120, and also a number of mineral concessions that are awaiting development. The Rhodesia Copper & General Exploration & Finance Co. owns shares in the subsidiary companies valued at £156,790, and has investments in other companies and in government stocks of £127,446, and many other extensive properties awaiting development. At the Bwana M'Kubwa, 12,552 ft. of development has been done to date. Above the 350-ft. level the ore reserve consists of 120,000 tons of 14% ore, and 750,000 tons of 5% ore, all oxidized. Experiments have been conducted in London with a view to finding the best process for the treatment of this ore, and an electrolytic leaching method has been adopted. The first part of the plant, having a capacity of 75 tons of high-grade ore per day, has been ordered, and should be at work before the end of the year. Further exploration at depth has disclosed large masses of sulphide ore, 'disseminated chalcocite,' and between the 350 and 550-ft. levels it is estimated that the probable ore is 2,500,000 tons of unspecified grade. The Kafue Copper Co. owns a number of properties in the hook of the Kafue river, the Sable Antelope and the Silver King being the principal claims. A 25-ton smelter erected at the former started work in August 1911, and during the eleven months to June 30 produced 1990 tons of matte averaging 72% copper, and containing 70,000 oz. silver. Owing to the cost of transport this matte has not yet been shipped. The reports as to the future of these properties are not quite reassuring. The results of development at the Silver King are not hopeful and work has been suspended. At the Sable Antelope the development disclosed 7000 tons of ore averaging 16% copper and 5000 tons averaging from 4 to 5%. The high cost of operations, and of transportation, together with the royalty payable to the British South Africa company make it doubtful whether work can be continued.

## General Mining News

### ALASKA

#### CORDOVA

At a depth of over 100 ft., sylvanite, a telluride of gold, assaying high, has been found in the claim owned by D. Ross, J. Foster, J. C. Clarkson, and C. Garwood, near Teikhell, on the Valdez-Fairbanks road. The vein has well defined walls, and is from 12 to 24 in. wide. Up to this time, only free gold had been found in the ore. A number of teams, loaded with provisions and mining supplies, have started for the new camp. Ten to twelve feet of pay-ore has been opened up at 200-ft. depth in the Mayfield properties. About 400 tons has been stored. It is proposed to erect a plant consisting of a crusher and Chilean mill. At Katalla the Amalgamated Development Co. is drilling to a 4000-ft. depth to test for oil-sand. About 35 bbl. is being produced daily from three wells. The Royal Development Co. intends to drill 3500 feet.

#### FAIRBANKS

From two clean-ups on the Biglow ground, on the left limit of Goldstream, \$55,000 has been won. One of the winter dumps has been sluiced, while the other dump contains a fair tonnage. Water conditions are not very good. It is estimated that the claim will produce \$500,000 this year. A four-stamp mill is being erected at the Fey Quartz claims at the head of Chatham creek. This mill will be the fifth on the Cleary divide.

#### KENAI PENINSULA

The ground along the Kenai river is to be thoroughly prospected for dredging purposes by Milnor Roberts and Wernecke, who have brought an Empire drill for the work. The Towle ground will be tested first, this being below the Cunningham group, between the lakes. Several promising properties on Mineral creek, known as the Big Four group, have been sold to California mining men, the purchase price being \$100,000. Within 70 days, \$4000 is to be paid, the balance to be paid in royalties at 25% gross yield. Little work has been done on the claims.

#### JUNEAU

During June, the 120-stamp mill of the Alaska Mexican worked 29.73 days, driven by water-power, and crushed 19,299 tons of ore. The gross value of the free gold saved was \$30,289, and the yield from 384 tons of concentrate being \$34,619, making the month's production \$64,908, of an estimated realizable value of \$64,259. After deducting operating, \$28,399, and construction expenses, \$7705, there remained a profit of \$28,155. The yield per ton was \$3.36. Development totaled 190 ft., and the stock of crushed ore increased 12,948 tons. The Alaska United Ready Bullion mill worked 29.73 and the 700-Ft. Claim mill 29.60 days, and crushed a total of 37,252 tons, from which 855 tons of concentrate was saved. The free gold was valued at \$49,988, and the concentrate yielded \$53,418, making a total of \$103,406. Deducting operating and construction expenses, the net profit was \$48,714. The yield from the Ready Bullion claim was \$2.79, and the 700-Ft. Claim \$2.76 per ton. Development in the former totaled 206 ft., and in the latter 471 ft., the stock of broken ore increasing 9553 and decreasing 2019 tons, respectively.

### ARIZONA

#### COCHISE COUNTY

A smelting plant to cost about \$500,000, with 400-ton capacity, is to be erected near Douglas by the Shattuck-Arizona company. Mine development continues encouraging.

#### GILA COUNTY

(Special Correspondence.)—Drill-hole No. 2 of the South Live Oak Development Co., three miles west of Miami, is over 775 ft. deep, and is in granite. It is stated that silicates and carbonates of copper have been found in

small quantities, but no chalcocite is reported. At the Southwestern Miami, churn-drill holes No. 6, 7, and 8 are 725, 615, and 540 ft. deep, respectively, and are all in mineralized schist, carrying more or less silicate of copper. Hole No. 8 is the one nearest to those already drilled, and it is in this hole that ore is first expected, though the chalcocite zone will probably not be reached for another month. The main west working shaft at the Inspiration Consolidated mine is over 200 ft. deep, and is being sunk at the rate of 5 ft. per day. During July it was sunk 164 ft., which is said to be the state record for a three-compartment shaft. Sinking the Scorpion shaft has been discontinued at a depth of 545 ft., and the Live Oak No. 2 at a depth of 1181 ft. A pumping station is being cut at the 1160-ft. level. Live Oak No. 1 shaft is being sunk, and is 496 ft. deep. Development is proceeding at the rate of about 4200 ft. per month. The new dormitory and mess-house for the members of the staff are nearing completion, and a new office building will be erected near the millsite. H. Kenyon Burch is working on the plans for new construction.

At the Superior & Boston mine a new stope is being opened on the sixth level, and it is reported that samples assay from 15 to 16% copper. Two stopes are being worked on the Limestone vein, one on the second, and one on the third level, the vein being from 3 to 4 ft. wide. It is stated that the mine is in better condition to make regular shipments than at any time since shipping was resumed. On the twelfth level, the east cross-cut, 500 ft. from the shaft, is in schist, and the cross-cut being driven south toward the Limestone vein is in 410 ft. in database. At the Iron Cap mine on Copper Hill, driving is being done on the 650-ft. level, from the Williams shaft, on what is believed to be a continuation of the Old Dominion vein. The west drift is in 310 ft., and the east drift 95 ft. On the 800-ft. level the drift is being continued west, and is in 110 ft. Jones & Danum have taken a lease on the claims of the Sleeping Beauty Copper Co. in the Sleeping Beauty mountains, seven miles northwest of Globe. There are 20 claims in the group, and the ore found carries gold, silver, and copper.

#### PINAL COUNTY

The Magma Copper Co. at Superior has just finished the erection of the last two boilers in the power plant, and as soon as the compressor is erected, operations will be conducted on a more extensive scale. Development continues to show rich ore. The American Smelting & Refining Co. is repairing the power-plant at the Lake Superior & Arizona mine, at Superior, and will soon begin unwatering and an examination of the mine. The Calumet & Arizona people, of Bisbee, are reported to have taken an option on the Cobre-Verde group of 81 claims at Superior, one mile south of the Magma mine. The option calls for a total payment of \$500,000.

Globe, August 1.

### CALIFORNIA

#### PLUMAS COUNTY

(Special Correspondence.)—The Crown Point, on Squirrel creek, has been taken on option by O. A. Eckman, of Denver. A thorough examination is being made, and if satisfactory a first payment will be made on August 15. C. A. Huntington has commenced work at the Comstock quartz property on the Winters creek. New York and New Jersey people are interested. The property was located three years ago by H. Kling, of Greenville. The vein is reported to average \$3 to \$20 per ton in gold. The Greenville Bullion Mining Co. is arranging for vigorous work at the recently bonded Bullion mine. Near the surface, veins averaging about 6 in. wide have been opened which assay from \$10 to \$45 per ton. A shaft at the mouth of the old adit is said to have cut 3 ft. of pay-ore at 18-ft. depth. The vein has been traced on the surface about 1000 ft. Credited as being the first quartz claim in the county, the Bullion has produced considerable gold in past years which was extracted from gravel and lodes. It is reported that a 10-stamp mill, hoist, and pumps will be erected soon. Electric power will be used. The mine is

situated about a mile west of Greenville, and residents of the town are chiefly interested. The 10-stamp mill recently erected at the Gruss mine is now working. Fox rifles are being used and are reported to be giving an excellent gold recovery. An electric generator and complete pumping plant have been erected. The mine is operated under lease by the Johnson-Locke Mercantile Co. of San Francisco. A R. Seymour recently shipped 1500 lb. of ore from his find to the Selby smelter. According to the owner, its value is estimated at about \$8000.

Quincy, August 3.

#### SHASTA COUNTY

(Special Correspondence.)—The Bully Hill Copper Co. is experimenting on the treatment of copper ore by electricity. A small plant has been erected at the Delamar smelter and tests are reported as encouraging. It is probable that an effort will be made shortly to treat the ore on a commercial scale. The Bully Hill ore carries a considerable percentage of zinc, and assays show it to contain gold and silver. The company was formerly one of the largest producers of copper in California, but the smelter has been idle since July 1910, owing to complaints that fume was damaging Government timber. The Bully Hill company later conducted tests to determine the feasibility of electrically extracting copper and zinc at the Heroult plant of the Noble Electric Steel Co. D. M. Rioridan is at Delamar inspecting the process. A new furnace is nearing completion at the Heroult electric iron smelter. Several improvements have been made and the company is arranging for steady production. A silver prospect known as the Silver King is being developed near Ono. A small quantity of good-grade ore has been opened. It is stated that the buildings recently destroyed by fire at the Little Nellie mine will be rebuilt at once. The property is idle at present. Attempts of certain farmers to cause the Mammoth Copper Co. further annoyance have so far been defeated. The company continues to liberally compensate for all proved damages resulting from smoke, and the majority of the farmers appear to be satisfied.

Redding, August 5.

### COLORADO

#### CLEAR CREEK COUNTY

On Columbia mountain the Animosa mine has opened a galena lode, which averages \$25 per ton. The mine is worked by an adit 1000 ft. long, and the ore is about 400 ft. from the surface. Electric power is used, as well as an air-compressor and machine-drills. Work at the Mineral Chief property is generally satisfactory. More men have been put at work on the Malm plant. The Kelly tunnel mill has started, and will be worked one shift only for a time.

#### SAN MIGUEL COUNTY

At the Smuggler-Union the company is erecting a large gyratory crusher at the mouth of the Bullion tunnel. The crusher will stand on a concrete pier about 18 ft. high. The Lewis mill, in Bridal Veil basin, has been started, and will work until the snow gets too deep to haul concentrate to Pandora. The shaft is down about 500 ft. at the mine, and 60 tons daily is being sent to the mill. An accumulation of over 300 tons of concentrate has been nearly removed. The Carbonero mine at Ophir is shipping five cars of ore per month to the smelter. Fifteen men are working at the alterations and additions to the Suffolk mill, worked by the Ophir company. The ore will be broken in a Blake crusher, and crushed by stamps through ¼-in. mesh screens. The pulp will pass a Dorr classifier, the oversize ground in a Hardinge tube-mill. All classifier overflow will be pumped to a Dorr thickener, the thick slime agitated with cyanide in a modification of the Pachuca agitator, further thickening, and the gold solution will be decanted. Zinc-dust precipitation will be used. The plant will have a daily capacity of 150 tons. Three machine-drills are working in the drifts, and two to four in the stopes. G. B. Pickett is manager for

the company. The Vanadium mines, at the west end of Montrose county, have been shut down, the reason being that the market was overstocked.

#### TELLER COUNTY (CRIPPLE CREEK)

According to local statistics, the output of the mines of the Cripple Creek district for July has totaled 76,410 tons, with a gross bullion value of \$1,226,224. As compared with the figures of the preceding month, an increase is shown of 2587 tons, and in value \$34,593. The feature of the month has been the tonnage treated at the Battle Mountain mill of the Portland Gold Mining Co. Ore of the low value of \$2.92 per ton was treated at the Argall plant on Stratton's Independence. Tailing from the old Isabella mill on Bull hill of the value of \$1.20 per ton was re-treated with profit. The figures reported by the smelters and mills are as follows:

Plant.	Tonnage.	Av. val.	Gross val.
Golden Cycle .....	33,150	\$20.00	\$663,000
Portland .....	10,000	22.00	220,000
Smelters .....	3,875	65.00	251,875
Portland (C. C. D.)....	14,950	3.38	50,531
Stratton's Independence.	10,835	2.90	31,638
Isabella .....	1,800	1.20	2,160
Wild Horse .....	900	3.80	3,420
Jo Daudy .....	900	4.00	3,600
	76,410		\$1,226,224

Great damage was done at Pueblo through a cloudburst on Tuesday last. Nearly an inch of rain fell in the first half hour, being the heaviest since 1889. The power-house was somewhat damaged, and fires were started at several places.

Seventy-three cars of ore, averaging \$25 per ton, were shipped from the Granite company's mines on Battle mountain during July. The tenth level of the Gold Coin shaft produced 14 cars worth \$30 per ton. Lessees on the ninth level of this shaft ship about seven carloads monthly, assaying up to \$50 per ton. On account of heavy rains, the water in the shaft has risen 10 ft. in 14 days. The C. K. & N. mine, on Beacon hill, shipped 20 cars of ore which returned from \$20 to \$30 per ton. The flow of water from the Roosevelt tunnel is now 10,000 gal. per minute, against 9600 gal. a fortnight ago. This increase is probably due to heavy seepage into the mines.

The W. P. H. mine, on Ironclad hill, produced 10 cars of milling ore from one of the shoots opened some time ago, and the Union Leasing Co. shipped 13 carloads from the Husted shaft of the Mable M. and 14 cars from the Gold Sovereign on Bull hill. The ore assayed from \$8 to \$50 per ton.

About 60 cars of ore were shipped by the Vindicator mine, and 35 cars from lessees during July. Development of the south vein system on the 1500-ft. level has opened six separate veins in that part of the mine. The Mary McKinney produced 37 cars averaging \$35 per ton. The shaft is down 905 ft. From the Duncan and Camduff lease 19 cars realized over \$50 per ton.

### MICHIGAN

For the six months ended July 1, the Ahmeek company crushed 315,003 tons of rock yielding 7,779,023 lb. of copper, equal to 24.7 lb. per ton. The cost per ton was \$1.38, and per pound of copper produced, 7.44c. Net earnings amounted to \$690,000. The Tamarack company produced 4,130,022 lb. of copper for the first half of the year. The yield was equal to 19.8 lb. per ton of rock crushed, and cost per pound of copper, 12.41c. The Isle Royale company produced 4,129,678 lb. of copper from 259,410 tons of rock for the half-year, the yield being 15.9 lb. per ton crushed, and costs 11.01c. per pound of copper. The Quincy produced 10,500,000 lb. of copper for the same period, the net profits being \$367,500.

During July the Champion mine yielded 2,490,000 lb. of copper; Tri-mountain, 846,000 lb.; and the Baltic, 1,852,000 pounds.

**MONTANA****SILVERBOW COUNTY**

The Federal Court has issued an order restraining the directors of the Alice G. & S. M. Co. from transferring the property to the Anaconda Copper Co., as was voted against by the minority stockholders of the Alice company. These stockholders say that fraud was practised, and the claims were sold to the Anaconda company for less than their actual value. The directors claim that at the time of the sale the Alice was of small value. It had paid \$1,500,000 in dividends up to the time of closing down in 1905. The Butte Coalition M. Co. bought a controlling interest in 1906; and in May 1910, a large majority of stockholders voted to sell to the Anaconda at the ratio of 15 shares of the Alice for one of the Anaconda.

**NEVADA****CHURCHILL COUNTY**

The June return from the Nevada Hills company, at Fairview, was \$104,561 from 3450 tons of ore treated. Costs

NEVADA HILLS MILL.

totalled \$33,460, leaving \$71,101 profit. The net costs for June were \$9.70 per ton, and \$1.36 below those of May.

**CLARK COUNTY**

Rich ore has been found at the Fortuna mine, in Eldorado canyon, and shipments are being sent to the International smelter at Tooele, in Utah. Six men are employed and over three tons per day of silver chloride ore is being mined. Further work has been started about 300 ft. east of the shaft, in a small gulch where there was an outcrop of ore. A report has been made on the Empire mine, and it is expected that work will open plenty of pay-ore.

**MINERAL COUNTY**

The Grey Horse shaft is down 30 ft., and copper has been cut 18 in. wide, assaying 19 oz. silver per ton, and 15.5 and 12.75% copper. A shipment will be made to the Thompson smelter. At the Luning Dude, good copper ore has been found 52 ft. from the Dillabough shaft. The Shipper company's shaft is down 56 ft., and five cars of copper ore were dispatched to the Thompson smelter, with a satisfactory return.

**NYE COUNTY**

At Manhattan it is reported that rich ore has been found in the Mustang, Mineral Hill, in the new shaft of the Crescent, the Dexter-Union, on the 150-ft. level of the Kendall-Douglass lease, ore has been proved for 200-ft. length by over 3-ft. width, and of a high value, on the 250-ft. level at the Mushett-Wittenberg lease, and Bath brothers have cut high-grade ore in their shaft. The adit at the Columbia claim is in 110 ft., and the Morning Glory shaft is down 75 ft. At the Big Four the drift on the 500-ft. level is out 150 ft. and the lode is reported to be 30 ft. wide.

During the past week the output from the Tonopah mines totalled 1080 tons, with an estimated value of \$270,025, the contributors to the total being the Tonopah Mining Co., with 4100 tons; Belmont, 3755 tons; Montana-Tono-

pah, 981 tons; Tonopah Extension, 1055 tons; West End, 850 tons; Midway, 40 tons; and North Star, 50 tons.

**STOREY COUNTY**

Summaries of the past week's reports for the Comstock mines state that the Ophir shipped 332 tons of second-class ore to the Kinkadee mill. On the 2500-ft. level, the west cross-cut from the southwest drift is in 78 ft., the face being in porphyry; while the cross-cut on the 2100-ft. level is in 79 ft., also in porphyry. Stoping on the 2400-ft. level of the Con. Virginia, 375 ft. from the mouth of the southwest drift, 30 tons, assaying \$19.62 per ton, was broken out. The west cross-cut on the 2300-ft. level is now in 203 ft., in quartz and porphyry of low grade. The Mexican mill crushed 510 tons of ore averaging \$26.26 per ton, with 93% extraction. One hundred and sixty-nine tons was stoped on the 2500-ft. level, north drift, which averaged \$26.08 per ton; and 37 tons from the main vein assaying \$131.81 per ton. From the north drift, No. 3, at the 2400-ft. level, 125 tons assayed \$18.27; and No. 2 gave 206 tons, worth \$20.76 per ton. At the Union Con. timbering is being done on the 2500-ft. level; also jointly with the Sierra Nevada and Mexican companies, timbering and ladders have been put in the air connection to the 2000-ft. level from the west vein stope of the latter mine. The joint winze of the Best & Belcher and Gould & Curry is down 155 ft. below the 1700-ft. level in porphyry, with clay and veins of quartz. Diamond-drilling is under way on the 2000-ft. level on the Julia Con. The water in the Yellow Jacket shaft is now 40 ft. 9 in. below the 1400-ft. station. The shaft is still being repaired. At the C. & C. pumping shaft, the water is 297 ft. below the 2200-ft. station, the Reidler pumps working 158.75, 168, and 166.75 hr., respectively, and No. 1 elevator 162.25 hr. In the Ward shaft the west cross-cut on the 1600-ft. level is cut 200 ft., while that on the 2000-ft. level was extended 15 ft. The Starrett pump was repaired. A miner fell a distance of 115 ft. below the 2000-ft. level in the Ward shaft and was killed. He was working in the shaft at the time. The verdict at the inquest was one of accidental death.

**OREGON****BAKER COUNTY**

At present no underground work is being done at the Ben Harrison mine. Surface work consists of road-making, erection of power transmission line, and grading for the reduction plant. The mill will be of 200-ton capacity, and is to contain 20 stamps, tube-mill, and filter-presses. Motors will be used throughout the plant.

**TEXAS****LLANO COUNTY**

(Special Correspondence.)—The asbestos deposit at Llano, which has been acquired by the National Asbestos Refining Co. of Chicago, is stated by the vice-president of that company, F. S. Ingram, to be of great extent. He is at present examining the deposit with mining men, and has had 15 men prospecting for some weeks. Test holes have been put down from 40 to 52 ft. deep, and at no point has the bottom been reached. The deposit is about 500 ft. wide and over 1700 ft. long, and outcrops over 60 acres. The mineral near the surface is somewhat weathered, but has long fibres at depth. A plant is to be erected to deal with a large tonnage of the product.

Austin, August 1.

**UTAH****JUAB COUNTY**

The half-yearly report of the Chief Consolidated company shows that 7968 tons of ore was shipped, averaging 0.24 oz. gold per ton, 46.22 oz. silver, and lead 3.73%, equal to a gross value of \$34.25 per ton. Sampling, freight, and smelting cost \$8.88 per ton. Sales of ore realized \$202,182, and net profit after paying all charges was \$1486.04. The balance on hand is \$152,108. Development totalled 1264 ft. The mine shows promise at many points, and a still further increase of tonnage may be expected.

## SALT LAKE COUNTY

Work has been resumed on the transport and drainage tunnel under the Oquirrh mountain range at Bingham. The Bingham Copper Tunnel Co. has absorbed the Bingham West Dip Tunnel Co., and will continue the work. The tunnel will be 20,000 ft. long, and will open at the mouth of Pine canyon in Tooele valley. Its course will then be southeasterly. Under the top of the range a lateral tunnel will be driven out to Markham gulch, in lower Bingham, above the Denver & Rio Grande railroad station. This tunnel will be 7000 ft. long and used mostly for transportation purposes. The main tunnel will pass under Bingham canyon and mines on the other side. A powerful tunneling machine is to be procured to push the work. At present the face is in 2000 ft. Cost of transporting ore should be greatly reduced. The tunnel will connect with the Utah Copper Co.'s mine at a great depth, and also the Boston Consolidated, Phoenix, and many other mines.

A fire at Bingham destroyed \$50,000 worth of the business area of the town. Eighteen rolls are working in the Ohio company's mill.

## SUMMIT COUNTY

During the quarter ended June 30, the Daly-Judge mine produced 16,017 tons of concentrating and 652 tons of shipping ore, the latter averaging \$26.43 per ton. There were 2785 tons of lead, and 2250 tons of zinc concentrate sold, averaging \$36.72 and \$25.60 per ton, respectively. The earnings were \$77,202 and \$45,000 paid in dividends, while the cash balance totals \$501,980. Mine conditions are satisfactory, and deeper development is now easier done, on account of the agreement entered into with the Daly West and Ontario companies in connection with the water difficulties. During July the Chief Consolidated company shipped 52 cars of ore. The Silver King Coalition Mines Co. has filed a suit against the Keystone Mining Co., in which the former seeks to quiet title to rights in the Red Fox, the U. J. Wenner, and the Bruser lode claims, all patented and located in the Park City district, to which the defendant is stated to claim title. The Silver King company owns the Pinyon, Pinyon Extension, Boss, Brave Columbia, Constitution, Cumberland, Monroe Doctrine, and Zephyr claims, and the lode on these claims on its course, and at its apex, crosses the east end of the Boss claim for 484 ft., and it also crosses the south side line of the Pinyon and Extension claims, on through others mentioned, into the claims in dispute. The report on the Park City district by the Geological Survey is at last issued.

## WASHINGTON

## SNOHOMISH COUNTY

(Special Correspondence.)—Mining operations are somewhat active after about two years' depression. The Hidden Treasure claim, in the Sultan river district, has been opened, and a lode 20 ft. wide has been found, assays running from \$4 to \$57 per ton. The vein is in slate. The divide between Olney creek and the Sultan river has been prospected of late, but the heavy undergrowth of brush is a handicap. A large outcrop has been found south of the Hidden Treasure. Twenty men are at work on the Florence-Rae copper mine. Ten feet of chalcopyrite has been opened on the Marguerite vein, and an analysis from a large sample gave 18.5% copper, 12 oz. silver, 35.8% sulphur, and 29.6% iron. Higher up on the mountain is another big outcrop. The country is composed of andesite, serpentine, and granite. Several other copper claims are being prospected in the vicinity. The Arnold Engineering Co., of Chicago, has completed preliminary work, in the Sultan district, on a hydro-electric project. By a series of six reservoirs, 106,000 hp. can be developed. The estimated cost of power-plant, water-supply, and railroad is \$5,630,000. It is probable that Seattle may take an interest in this project. An air-compressor and drills have been erected at the Eclipse mine, near Silverton. Work is under way from 200-ft. depth. The ore carries silver and copper. The Sunrise group of copper claims on Vesper

creek has been examined by an engineer said to be working for the Guggenheims.

Everett, August 1.

## WYOMING

## ALBANY COUNTY

A shipment of ore from the Rambler mine has been sent to the testing plant of H. E. Wood, at Denver. A new process of centrifugal concentration is being tried on the recommendation of Leo von Rosenberg.

## AUSTRALASIA

## BENDIGO (VICTORIA)

During the week ended June 24, 23 mines yielded 3944 oz. bullion, and for the fortnight ended this date, 24 other mines produced 824 oz., including returns from tributaries. Dividends paid totaled \$27,500. Among the principal producers were the Catherine Reef, with 164 oz. from 524 tons; Central Red, White & Blue, 355 oz. from 625 tons; Golden Pike, 85 oz. from 179 tons; Johnstons Reef, 242 oz. from 395 tons; New Shenandoah, 200 oz. from 50 tons; private mines and pyrite treatment companies, 650 oz.; United Hustlers & Redan, 337 oz. from 287 tons; New Chum Goldfields, 35 oz. from 222 tons; Garden Gully, 8 oz. from 68 tons; Koch's Pioneer tributaries, 204 oz. from 70 tons; and South New Moon, 138 oz. from 410 tons. Bendigo bullion is worth about \$19.50 per ounce. The north stopes on the 2300-ft. level of the Catherine Reef are producing the bulk of the output. Ore at the Central Blue is being won principally from the 318 and 400-ft., north, levels. In the Golden Pike the east leg of the reef on 447, 543, and 643 ft. is rather erratic in gold content. At the New Shenandoah, the west leg is 24 in. wide at 565 ft. United Hustlers shows a reduction in output on previous weeks. The raise above the 500-ft. level is improving. The Garden Gully has a good deal of ore at 790-ft. depth. Generally, the returns are satisfactory, and shares have been freely dealt with.

## CANADA

## BRITISH COLUMBIA

According to a description of the Nickel Plate mine and works at Nelson, published in the *Hedley Gazette*, the ore is drawn from the lower tramway bin, direct to a 10 by 20-in. Farrel crusher, from which it passes over a grizzly, the coarse portion passing a 6 by 20-in. Farrel crusher. All the broken ore goes by belt-conveyor to the storage bins. Challenge feeders deliver to the 40 stamps, which weigh 1050 lb. each, and drop  $7\frac{1}{2}$  in. 101 times per minute. No amalgamation is attempted on plates. The screen on the mortars is 12 by 12, and the stamps crush 5 tons each per day. The pulp passes through four spitzkasten, one portion of the underflow going to 8 corrugated-belt Frue vanners, and the other to 16 smooth-belt vanners and 12 Deister tables. The tailing from the first vanners is ground in a tube-mill. All the pulp flows to cone-classifiers, from which the slime and sand go to their treatment plants. About 240 tons of concentrate is produced per month. This contains 70 to 80% of the gold content, and is shipped to the Tacoma smelter. The slime is agitated 12 hours with cyanide, settled, and then treated in Oliver presses. The sand is leached in a double treatment plant of 12 vats, 6 by 32 ft., for 20 days. Gold is precipitated with zinc-dust in Merrill presses. About 95% extraction is obtained. The monthly capacity of the mill is now 6000 tons. Electric power is generated by water or steam plants.

The Granby company smelted 739,519 tons of ore during the year ended June 30, and of this quantity 17,800 tons came from other properties. A comparison between the term just ended, and the previous one shows the following:

	Copper, lb.	Silver, oz.	Gold, oz.
1911 .....	17,858,860	343,178	41,707
1912 .....	13,266,360	255,723	33,946

The reduction in output was caused by the strike of coal miners in western Canada, resulting in the smelter being shut down for 122 days in 1911. The present rate of production is about 1,900,000 lb. of copper per month.

The Canadian Government has completed soundings of the waterways near Hidden Creek, and the channel into Granby is being marked. The ore docks, smelter, and power-plant of the Granby Con. M. & S. Co. are there. Three steamship companies will have a regular service between Granby bay and Seattle, Vancouver, and Victoria. Two hundred men are working in the Hidden Creek mines, which are looking well. Between four and five million tons of ore is in sight, and diamond-drilling is proving more. The power-plant, smelter, and other equipment should be working within a year.

## ONTARIO

The first clean-up from the Hollinger mine is reported to have been valued at \$41,000, and is considered satisfactory. The winze being sunk from the 200-ft. level is finished, and a station is being cut on the 300-ft. level. That section of the mill containing the concentrators and pans is being partitioned off from the rest of the plant.

The members of the Porcupine miners' union notified nearly all the mine managers in the district that they were applying to the Department of Labor for an appointment with the conciliation board, to settle matters in dispute between the men and managers. The question is the adoption, by the mines, of a new scale of wages to come into effect on August 1, whereby the men at the small mines are to be paid the same rate as those at the Dome and Hollinger. This new scale, adopted by the managers, gives all men 25 cents higher per day than the rate paid at Cobalt.

The quarterly report of the Wettlaufer mines, at South Lorrain, shows that 621½ ft. of development was done. No new lodes were found, but the Silver Eagle continued to open in a satisfactory way. A winze is being sunk 100 ft. below the 400-ft. level. During the period ended June 30, 4166 tons of ore was treated at the mill. From the mill and shipments 198,711 oz. of silver was produced, which returned \$120,787, and the profit was \$71,737.

## MEXICO

The seventh annual report of the Mexican Light & Power Co. states that the gross earnings for the year ended December 31, 1911, totaled ₧7,581,027. Operating expenses and maintenance amounted to ₧2,195,028, which left net earnings at ₧5,385,999. Dividends of 7% were paid on the preferred shares, and 4% on ordinary shares. The reserve fund totals ₧855,766, and balance to credit of profit and loss is ₧1,968,254. The directors report that, beyond the breaking of a few are lamps by unruly crowds, none of the company's property was interfered with, and the business has progressed in spite of the disturbed condition of the country. The increase in the sale of power has been satisfactory, a large part of the increased demand coming from the Pachuca district. Good progress is being made in the construction of reservoirs, dams, and tunnels.

## CHIHUAHUA

(Special Correspondence.)—During the quarter ended June 30 the La Republica mine crushed 2107 tons with a yield worth ₡158,366. Operating costs totaled ₡125,343, and construction ₡11,278. The management reports that labor conditions continue to be unfavorable, owing to the revolution having drawn away most of the workers from this section; consequently the mill cannot get a full supply of ore.

Chihuahua, July 26.

## JALISCO

The United States Smelting, Refining & Mining Co. has taken an option for purchase on the San Pedro Anasco silver mines, situated in the Hostotipaquillo district of Jalisco. The price is stated to be ₱750,000, and the term is for one year, during which time the company must spend ₱75,000 on development. The company controls the Real Del Monte y Pachuca property, in the Pachuca district of Hidalgo. The San Pedro mines were examined by Ezequiel Ordoñez, the company's geologist. A small mill is already at the mines. The building of a branch transmission line from the main Hostotipaquillo line of the Chapala Hydro-

electric & Irrigation Co. to the Cinco mines is being pushed ahead. A 50-ton capacity smelter has been sent to the Mexicana mine, and it is to be in operation toward the end of the year. The concentrating plant will be re-started at an early date.

## PHILIPPINE ISLANDS

## MANILA

According to the *Far Eastern Review*, a dredge has been ordered from Melbourne for the Squires gold mining property, situated on the Umarai river. The hull will be of steel and of a new design, and the buckets will be attached to a large wheel, instead of the usual ladder. The machine complete will cost \$100,000. Australians have invested about \$250,000 in this property. The O. K. com-

THE PHILIPPINE ISLANDS.

pany has been formed, with an office at Baguio, to work its claims in the Benguet mountains. Operations have been resumed at the Headwaters mines district, northwest of Baguio. The Luzon Gold Co. has started sluicing some bench claims. Water is carried a distance of 1500 ft., and 2000 ft. of hose was ordered from the United States. This company has large areas of placer holdings which can be dredged and sluiced. A 50-ton sample of coal from East Batan was recently sent to the U. S. Government Bureau of Mines testing plant at Pittsburg. The report says that, when received at Pittsburg, the coal contained 60% of slack, 15% of lump, and 25% of small lump, which reduced its steaming value. The average run-of-mine coal contains 60% of lump, large and small. The Batan coal evaporates 20% less water than the best Japanese, and 30% less than the best Australian coals, but it equals the Labuan (Borneo) coal, which is shipped in large quantities. The Batan mine can produce 5000 tons monthly at a cost of ₱7.20 landed at Manila.

## Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

THOMAS T. READ is at Butte.  
M. L. REQUA is back from Alaska.  
D. M. RIORDAN is in San Francisco.  
ARTHUR L. SWEETSER is in Honduras.  
G. H. CLEVENGER has gone to Denver.  
W. C. OREM has been in San Francisco.  
C. C. BROADWATER is at Porcupine, Ontario.  
J. B. KEATING has returned from New York.  
H. B. KAEDING is visiting friends in Chicago.  
EDMUND JUESSEN has returned from Oregon.  
B. L. MILLER was in San Francisco Thursday.  
FRED T. WILLIAMS left for Alaska August 9.  
C. W. MERRILL has returned from Lake Tahoe.  
J. NELSON NEVIUS was in San Francisco this week.  
W. H. STORMS has gone to High Grade, California.  
R. A. F. PENROSE, JR., was in San Francisco this week.  
ALBERT BURCH has returned from Carson City, Nevada.  
WHITMAN SYMMES is expected in San Francisco this week.

C. F. TOLMAN, JR., has been appointed associate professor of geology at Stanford University.

F. L. SIZER has gone to Arizona and will visit Globe before his return.

PHILIP WISEMAN was in San Francisco Monday, returning from a trip around the world.

FREDERICK G. CLAPP has returned from the Canadian oilfields and gone to West Virginia.

JOHN G. WORTH is on a professional trip in New Mexico, Arizona, Nevada, Montana, and Colorado.

GEORGE H. BOOTH is now at Miami, Arizona, as chief draughtsman for the Inspiration Con. C. Company.

J. W. MERRITT, assistant in mineralogy at Northwestern University, has been appointed instructor in geology at Dartmouth College.

H. F. WIDDICOMBE, general superintendent for the Day-Bristol Con. M. Co., at Pioche, Nevada, was married at Salt Lake City, July 29.

L. E. IVES has resigned as associate editor of the *Engineering & Mining Journal* to become mining and assistant engineering editor of the *Iron Trade Review*.

GEORGE H. ASHLEY, who recently returned to the Government service after organizing the Tennessee Geological Survey, has been appointed administrative geologist of the United States Geological Survey.

THOMAS H. LEGGETT has become consulting engineer for the A. S. & R. Co., and his address will hereafter be 165 Broadway, New York. The firm of Leggett & Hellmann being dissolved, FRED HELLMANN will continue the business in his own name at 60 Broadway.

ALEXANDER N. WINCHELL has resigned from the U. S. Geological Survey in order to resume work as a consulting mining geologist. He has recently returned to his office in Madison, Wisconsin, after spending several weeks in Nevada in connection with litigation regarding the National mine.

## Copper Producers' Association Report

The Copper Producers' Association reported copper stocks on August 1 as 50,280,421 lb., against 44,335,004 lb. on July 1. Production: July, 137,161,129 lb., and in June, 122,315,240 lb. The July foreign delivery was 60,121,331 lb; June, 61,449,650 lb. Domestic deliveries: July, 71,094,381 lb; June, 66,146,229 lb. Total delivery: July, 131,215,712 lb; June, 127,595,879 pounds.

James Lewis & Son's Copper Report

From June 17 to 20 the price of standard copper advanced from £79 2s. 6d. to £80 for cash. Owing to reports of the existence of hidden stocks in the United States, and profit taking by speculators, prices fell on June 24 to £76 10s.; but as the above reports were generally discredited, a recovery was made to £78 8s. 9d. on June 27. Closing prices on July 1 were £77 8s. 9d. cash, and £78 6s. 3d. for three months. Sales during the month of June totaled nearly 70,000 tons. Electrolytic copper has been sold up to £81 5s. per ton c.i.f.

European stocks have decreased 3227 tons, and the visible supply by 4452 tons, during the month. Imports into Europe from the United States in June total 26,457 tons, while the imports are 4452, and deliveries 2797 tons less than during the same period last year. Deliveries for shipment to Europe are much in arrears, and consumers have, as a result, drawn upon European stocks to some extent for immediate requirements. Large quantities of American refined copper have been sold for September delivery.

Imports into England and France for the month of June were 18,856, and deliveries 20,626 tons fine copper. Chilean copper arrived in England to the extent of 1986, and deliveries 1515 tons; while from other countries 9850 and 12,267 tons respectively. Liverpool and Swansea received from the United States 1812 tons of bars, 500 of plates, and 20 of matte, equal to some 2305 tons fine. In London 365 tons was received, and in France 6155 tons.

The Chilean charters for the month were advised at 4400 tons, including 2575 tons for the United States. The exports from the former country for the first half of the current year totaled 17,125 tons, against 15,370 tons for the similar period of 1911.

IN Illinois the value of the mine production of silver, lead, and zinc in 1911 was \$569,335, an increase of more than \$150,000 compared with the 1910 yield. The lead concentrates from the southern Illinois fluorspar district increased 84 tons in quantity, and the silver content recovered in treating the concentrates increased from 2022 fine ounces in 1910 to 3036 oz. in 1911. The Galena district, in north-western Illinois, showed an increased output of both lead and zinc concentrates. The lead concentrates in northern Illinois amounted to 787 tons, worth \$41,220, or estimating the metal content at New York prices, 625 tons, worth \$56,250. The zinc concentrates totaled 11,011 tons, worth \$320,806; equal to 4219 tons of spelter, worth \$480,966.

Including southern Illinois the lead concentrates amounted to 1269 tons, worth \$62,425, and equal to 964 tons of metal, worth \$86,760. No zinc was reported from southern Illinois, but silver equivalent to 6.25 oz. per ton was contained in the lead concentrates. The average lead content of concentrates from southern Illinois was 70% and the value \$44 per ton. In northern Illinois the total amount of crude ore was 153,313 tons. The percentage of lead was 0.4 and of zinc 3.2. Concentrates averaging 79.4% were made from the lead ore, while the zinc ore yielded concentrates averaging 45.3% zinc.

Goldfield Consolidated Report

During the month of June the total production of the Goldfield Consolidated Mines Co. was 23,365 tons, containing \$573,658.31, or an average of \$17.72 per ton. The mill treated 29,040 tons with an average extraction of 92.63%, and 3325 tons, of an average value of \$23.91 per ton, was shipped. The total net recovery from all ore was \$16.60 per ton, and the total net realization to the company was \$325,475.52, or \$10.06 per ton. Development for the month amounted to 3034 ft. In the Combination mine, the stope in the Reilly vein southeast of the shaft produced 1341 tons of ore that averaged \$22 per ton. The 402-G stope, 300 ft. north of the shaft, between the fifth and sixth levels produced 353 tons of ore averaging \$18 per ton. This is the deepest point in this mine at which ore has been found. A new stope which is expected to yield a large tonnage is being opened on the second level 200 ft. east of the 136 stope, under the old January workings. The 102-X and 103-X drifts driven through the quartz produced 117 tons of ore averaging \$15 per ton. In the Mohawk mine, the work north of the 3 stope on the 150-ft. level through the old Sheets-Ish ground has proved a large tonnage of good-grade ore. The 3-J sill, 50 ft. north of 3-E stope, produced 43 tons of ore that averaged \$37.60 per ton. The 29 drift was advanced north in the foot-wall of the Sheets-Ish stope and produced 38 tons of ore averaging \$31 per ton. The 170-L stope on the 250-ft. level stripped the lower end of the Sheets-Ish stope and produced 105 tons of ore which averaged \$28 per ton. The 111-N stope on the 250-ft. level under the Hayes-Monnette stope produced 354 tons of ore averaging \$40 per ton, and the 354-Q stope in the foot-wall section of the big 354 stope produced 1389 tons of ore that carried \$43.20 per ton. In the Clermont mine the 426 intermediate between the 750 and the 600-ft. levels, and close to the old 401 stope produced 108 tons of \$28 ore. The development on the 1300-ft. level of the Grizzly Bear was very satisfactory. The 802 drift in the orebody was shipped unsorted, and the last round of broken rock averaged \$64 per ton. The third compartment of the shaft from the 1300 to the 1000-ft. level had pipes, ladders, and electrical equipment moved over. Guides were put down the former runway from the surface to the 1300-ft. level, and a double-drum electric hoist placed on the surface. Sinking on the next 140 ft. was started.

The total cost of mining, development, transportation, milling, office, and general expense was \$6.82, distributed as follows:

Mining:	
Development .....	\$0.79
Stoping .....	2.51
	— \$3.30
Transportation .....	0.08
Milling .....	2.03
Marketing .....	0.06
General expense .....	0.47
Bullion tax .....	0.12
Marketing ore shipped .....	0.70
Construction .....	0.06
Total cost of operation .....	\$6.82
Miscellaneous earnings .....	0.06
Total cost per ton.....	\$6.76

## Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

**SUFFICIENT** agitation at some mills is achieved in the Brown agitator without the usual inch pipe hanging down the centre of the central air-lift to the bottom, or one fitted into the bottom from the outside.

**HYDRAULIC** filling was first employed in an unsystematic manner, as far back as 1883 in the Upper Silesia, and 1887 in Pennsylvania according to O. Puetz in the *Zeitschrift des Verbandes der Bergbau-Betriebsleiter Oesterreichs*, but in its present scientifically and technically perfected and systematized form it was first worked out and introduced in 1901 by Hr. Williger, director-general of the Kattowitz Mining Co., at the Myslowitz mine, in Upper Silesia.

**EUCALYPTUS** oil is being manufactured at Corang, N. S. W. A plant which had been in operation at Tarago has been removed to Corang. In place of the iron tanks which have been used hitherto for the purpose, it consists of an engine and boiler for heating the water in which the leaves are boiled. About 25 men are being employed in leaf-cutting. At Monka, 32 men are employed, at Fitzpatrick & Co.'s works, making about 60 altogether, with the firemen. As many more are probably engaged in the smaller plants in the district.

**LIFE** of steel elevator-buckets at Waihi, lifting 10-mesh pulp, was 50% less than when finer pulp was raised. Increasing the plate from  $\frac{1}{8}$  to  $\frac{3}{16}$  in. gave a life of about eight months. A wood bucket was tried with splendid results, then more buckets of different kinds of timber were tried and four months' work shows little wear. Two wheels of 35-ft. diameter were equipped with wooden buckets, at a cost of one-third of that of the steel buckets. The reason for the superiority of wood over steel in this case is somewhat hard to understand.

**ISOLATED** mines of any size should each have its own foundry and machine-shop. In Australasia, the mines at Kalgoorlie are nearly all so equipped, as is also true of Mt. Morgan, Mt. Lyell, and Waihi. A large quantity of iron, steel, and brass scrap accumulates, especially from mills, and this can be more profitably melted at the mine and cast as required, than sold as scrap. This has often been proved. Besides, a break-down can be quickly repaired, the shops being on the spot. Although the jobs may not be always so good as when done elsewhere, the cheapness of such repairs pays for an extra number of spare parts.

**SUMMING** up the difficulties of cyaniding antimonial tailing, the following are the chief points to be watched. (a) The strength of the working solutions so that the selective action of the gold will be at a maximum while the solution of the sulphide of antimony is at a minimum, also the consumption of cyanide; (b) the amount of protective alkalinity present; this must be such that the consumption of cyanide is kept down; yet it must not be too pronounced, as in that case the solution may dissolve the sulphide of antimony and refuse to take up the gold present; (c) treating the precipitate, which always contains more or less antimony in metallic form; (d) the final production of clean gold.

**ARSENIC** salts and oxides in large number are used medicinally, among them the bromide, iodide, trisulphide, trioxide, sodium arsenate, and potassium arsenate. Disulphide of arsenic, both natural and artificial, is used as a paint pigment; in calico printing and dyeing; in tanning; and, as it burns with an intense white light, in fireworks.

Orpiment, the trisulphide, called also king's yellow, is used as a paint pigment and as a reducing agent in chemical work. The trioxide is used in paints; for preserving hides, both for taxidermists and in the leather industry; as an antiseptic; and in killing animal pests. Sodium arsenate is used in dyeing with turkey-red oil and in printing fabrics; the arsenite in making soaps for use on skins and hides. Potassium arsenite is used as a reducer for silver in the manufacture of mirrors.

**FUEL** briquetting in the fields of non-coking coal in the Middle West has to meet the low price of the raw fuel with which the briquette has to compete. The average price for fuel in the northern Middle states in 1911 ranged from about \$1.10 to \$1.75. The cost of manufacturing briquettes, exclusive of the cost of the raw material, is about \$1 per ton, and although briquettes possess undoubted advantage for domestic use over raw coal, householders have to be educated to the fact that the higher cost of the briquettes is more than offset by their desirability. In Germany the briquetting industry has made extraordinary progress, the production in 1910 being 16,668,605 short tons, and in 1911, 18,551,020 tons. Some probability of more substantial development of briquetting in the Eastern states is indicated by the recent advance of 25c. per ton on the domestic sizes of anthracite and the fact that there is little possibility of any future reduction in the prices of this fuel. In fact, further advances are more to be expected, in view of the rumored increase in royalty to be demanded by the owners of coal lands in the anthracite region.

**DEPOSITION** of metals of any character upon any insoluble surface by electrical energy has been perfected by two Italian chemists. The results so far achieved promise to revolutionize the whole art of electroplating as well as many other branches of industry. China, wood, glass, celluloid, paper, and other substances which have hitherto been regarded as beyond the electroplater's craft are coated as easily as the metals generally associated with this process. The plating enters into the fabric treated so that it becomes an integral part of the article. Thus, for instance, if an attempt is made to chip the plating from a glass vase the glass will come away with its metal coating. The outer sheathing is not a thin film, but a solid sheet of metal which can be made of any thickness and capable of being worked by the engraver. The authorities have expressed their willingness to apply the hall mark to articles so mounted. The process is likely to supersede the present process of silver-mounting cut glass and other articles. Instead of the metallic adornment being attached by means of plaster of paris, which is simply a make-shift, the metal deposited upon the glass becomes part and parcel of the article. Any metal and its alloys can be electrically deposited upon some other metal as a base. Zinc, tin, and lead can be deposited as easily as silver or nickel. This fact is of vital interest to a host of industries, as is borne out by the action of one of the largest builders of naval vessels, who has adopted the process for the zinc and tin plating or galvanizing of the steel parts of the boats. The deposit is not so thin, as in ordinary galvanizing, that a pin scratch will penetrate the protective skin, but is a solid sheathing of metal associated with the other metal beneath. Wooden articles are as efficiently plated by the Marino process as if copper were being plated. So far as china plating is concerned, the article must be in the unglazed or biscuit condition, and is first coated with a chemical agent. In the same manner glass which is to be treated must first be roughened by sand-blasting to remove the polish and to enable the metal to secure a grip. Another point is that the deposit, no matter what the character of the base, may subsequently be oxidized or lacquered in just the same way as ordinary electrowork. The possibility of being able to deposit a protective coating upon aluminum, and thus save it from oxidation, will popularize the use of this metal in industries where, although it is urgently required by reason of its lightness, it is viewed with disfavor owing to its rapid corroding.

## Book Reviews

Any of the books noticed in this column are for sale by, or can be procured from, the MINING AND SCIENTIFIC PRESS.

**METHODS OF AIR ANALYSIS.** By J. S. Haldane. 128 pp. Ill., Index. Charles Griffin & Co., Ltd., London, 1912. For sale by the *Mining and Scientific Press*. Price \$1.75.

The author of this volume is well-known in the mining world through his investigations and his papers on hygiene, mine gases, and mine explosions. The work under review is a collection of useful methods for sampling air and gas and includes descriptions of apparatus for analysis, of processes of analysis, and of calculations of results. At the present time, when so many investigations are being conducted in coal and ore mines, relative to coal-dust explosions and miners' phthisis, the work is especially timely. Air and gases are peculiar compounds to deal with, and from sampling to testing, great care must be taken to ensure accuracy. At the same time, these analyses are no easy work, considerable skill being necessary. In the recent inquiry into gases from explosives in Western Australian mines, special care was shown. The iodine pentoxide method for determination of CO was used, and Haldane's apparatus for estimations of CO<sub>2</sub> and oxygen. 'Methods of Air Analysis' will be found to contain many notes from papers on the subject published in several journals, and not previously brought together.

**INTRODUCTION TO THE STUDY OF MINERALS.** By A. F. Rogers. 512 pp. Index. The McGraw-Hill Book Co., New York, 1912. For sale by the *Mining and Scientific Press*. Price \$3.50.

This handy little work is intended to serve as a text-book for a one-year course in mineralogy, and also for use in the field. The volume covers the subject in a concentrated form, so much so that it obviates the necessity for a student or mining man having several books on the subject. The work is essentially one for the student, as however important the form, physical, optical, and chemical properties of minerals are, and to these large space is given, these phases of the question would not be sought by the man in the field. He is mainly interested in description, occurrence, association, and uses of minerals. These are dealt with in a useful and interesting manner, but in less detail. There are a large number of figures for study, more especially of the crystalline forms of minerals, while useful chapters are given on hardness, specific gravity, and blow-pipe tests. Six tables are included in which minerals are arranged according to crystal system and habit; structure and cleavage; color; specific gravity; optical properties; blow-pipe; and chemical tests. The general form of these tables is good. The prospector will find the 131 pages devoted to a description of important minerals of much value, giving in a condensed form the essentials as to form, hardness, specific gravity, color, chemical composition, blow-pipe tests, uses, and occurrence. Twenty-three pages are taken up with a glossary of mineralogical terms.

**OIL FINDING.** By E. H. Cunningham Craig. 195 pp. Ill., index. Edward Arnold, London, 1912. For sale by the *Mining and Scientific Press*. Price \$3.40.

The author of this book states that it has been written for the younger geologists, but there are many who are old in the profession who might learn much from its reading. In successive chapters he discusses, The Origin of Petroleum; Processes of Formation; The Migration, Filtration, and Subterranean Storage of Petroleum; Lateral Variation; Geological Structure; Indications of Petroleum; Stratigraphy; Location of Wells; Field Work; Indoor Work. The author was formerly a member of the Geological Survey of Great Britain and has had experience in a number of foreign fields. He has produced a very readable book, full of suggestions based upon sound

common sense. His views on disputed points are pronounced, but are always clearly and frankly stated with an excellent array of evidence to back them. The book will be especially helpful to those making preliminary examinations of a field. It does not cover such work as is regularly done by many geologists in America who direct development in fields after they have been found. The making of structural contours and the use of a convergence sheet are, it is true, rarely possible in an untested field, though they made possible the finding of the Carlyle, Illinois, field and are in constant service in locating extensions in the Appalachian and other regions. Mr. Craig's book, none the less, is full of useful material and covers a field not otherwise served.

## Recent Publications

**REPORT OF THE SLUDGE ABATEMENT BOARD FOR THE YEAR 1911.** 38 pp. Plates, ill. Victoria, Melbourne, 1912.

**ANNUAL REPORT ON DREDGE MINING AND HYDRAULIC SLUICING FOR THE YEAR 1911.** 17 pp. Tables. Victoria, Melbourne, 1912.

**THE RUBY PLACER DISTRICT, ALASKA.** By A. G. Madren. Advance chapter from Bull. 520, 'Mineral Resources of Alaska, 1911.' U. S. Geol. Surv. Bull. 520-J. 14 pp. Map. Washington, 1912.

**THE ALATNA-NOATAK REGION, ALASKA.** By Philip S. Smith. Advance chapter from Bull. 520, 'Mineral Resources of Alaska, 1911.' U. S. Geol. Surv., Bull. 520-L. 25 pp. Map. Washington, 1912.

**THE PRODUCTION OF TIN IN 1911.** By Frank L. Hess. Advance Chapter from Mineral Resources of the United States, Calendar Year 1911. 12 pp. Tables. U. S. Geol. Surv. Washington, 1912.

**THE RAMPART AND HOT SPRINGS REGION, ALASKA.** By H. M. Eakin. Advance chapter from Bull. 520, 'Mineral Resources of Alaska, 1911.' U. S. Geol. Surv. Bull. 520-I. 20 pp. Map. Washington, 1912.

**GOLD PLACERS OF THE YENTNA DISTRICT, ALASKA.** By Stephen R. Capps. Advance chapter from Bull. 520, 'Mineral Resources of Alaska, 1911.' U. S. Geol. Surv. Bull. 520-F. 31 pp. Maps. Washington, 1912.

**THE CEMENT INDUSTRY IN THE UNITED STATES IN 1911.** By Ernest F. Burchard. Advance Chapter from Mineral Resources of the United States, Calendar Year 1911. 37 pp. Index, tables. U. S. Geol. Surv., Washington, 1912.

**GOLD DEPOSITS OF THE SEWARD-SUNRISE REGION, KENAI PENINSULA, ALASKA.** By Bertrand L. Johnson. Advance chapter from Bull. 520, 'Mineral Resources of Alaska, 1911.' U. S. Geol. Surv. Bull. 520-E. 47 pp. Map. Washington, 1912.

**VANADIUM DEPOSITS IN COLORADO, UTAH, AND NEW MEXICO.** By Frank L. Hess. Advance chapter from Bull. 530, 'Contributions to Economic Geology, 1911. Part I.' U. S. Geol. Surv. Bull. 530-K. 25 pp. Ill., map. Washington, 1912.

**SULPHUR IN UTAH, WYOMING, AND COLORADO.** By F. L. Hess, D. F. Hewett, E. S. Larsen, and J. F. Hunter. Advance chapter from Bull. 530, 'Contributions to Economic Geology, 1911, Part I.' 25 pp. Index, map, ill. U. S. Geol. Surv. Bull. 530-O. Washington, 1912.

**GOLD PLACERS BETWEEN WOODCHOPPER AND FOURTH OF JULY CREEKS, UPPER YUKON RIVER, ALASKA.** By L. M. Prindle and J. B. Mertie, Jr. Advance chapter from Bulletin 520, 'Mineral Resources of Alaska, 1911.' 12 pp.; map. U. S. Geol. Surv. Bull. 520-G. Washington, 1912.

**MINING AND WATER SUPPLY OF FORTY-MILE, SEVENTY-MILE, CIRCLE, AND FAIRBANKS DISTRICTS, ALASKA, IN 1911.** By E. A. Porter and C. E. Ellsworth. Advance chapter from Bull. 520, 'Mineral Resources of Alaska, 1911.' U. S. Geol. Surv. Bull. 520-H. 63 pp. Charts, tables. Washington, 1912.

## Coal Production in 1911

Final figures for the coal output of the United States in 1911 are given below, being those compiled by E. W. Parker, of the United States Geological Survey.

State or territory.	1911	
	Quantity.	Value.
Alabama .....	15,021,421	\$19,079,949
Arkansas .....	2,106,789	3,396,849
California and Alaska.....	11,647	13,297
Colorado .....	10,157,383	14,747,764
Georgia .....	165,330	246,448
Idaho .....	1,821	4,872
Illinois .....	53,679,118	59,503,278
Indiana .....	14,201,355	15,326,808
Iowa .....	7,331,648	12,663,507
Kansas .....	6,254,228	9,645,572
Kentucky .....	13,706,839	13,617,217
Maryland .....	4,685,795	5,197,066
Michigan .....	1,476,074	2,633,803
Missouri .....	3,760,607	6,431,066
Montana .....	2,976,358	5,342,168
New Mexico .....	3,148,158	4,525,925
North Dakota .....	502,628	720,489
Ohio .....	30,759,986	31,810,123
Oklahoma .....	3,074,242	6,291,494
Oregon .....	46,661	108,033

Tennessee .....	6,433,156	7,209,734
Texas .....	1,974,593	3,273,288
Utah .....	2,513,175	4,248,666
Virginia .....	6,864,667	6,254,804
Washington .....	3,572,815	8,174,170
West Virginia .....	59,831,580	53,670,515
Wyoming .....	6,744,864	10,508,863
Total bituminous .....	405,724,241	\$450,957,698
Pennsylvania anthracite .....	90,464,067	174,952,415
Grand total .....	496,188,308	\$625,910,113

## Commercial Paragraphs

The American Boston Mining Co., Diorite, Michigan, will install in its power plant a 500-kw. 2300-volt Curtis turbo-generator. The order for this unit has been placed with the GENERAL ELECTRIC COMPANY.

Reuben Bowen, who has been connected with the International Steam Pump Co., for over fifteen years in the capacity of district and department sales manager, and also general sales manager of the Fred M. Prescott Steam Pump Co. at Milwaukee, Wisconsin, and the Jeanesville Iron Works Co. of Hazleton, Pennsylvania, has resigned to accept the position of general sales manager of the EPPING-CARPENTER Co. of Pittsburg, Pennsylvania, manufacturers of pumping machinery.

THE DODGE MANUFACTURING CO., Mishawaka, Ind., reports that it has just closed a contract with the Alaska Treadwell Gold Mining Co., Treadwell, Alaska, for two 250-hp. Dodge rope-drives. One of these will connect a motor with a jackshaft, and the other will connect the air-compressor with the jackshaft. Also all the equipment, including rope sheaves and jackshaft material. The Dodge company has also received an order from the Consolidated Arizona Smelting Co., Humboldt, Arizona, for jig-drives, trommels complete with screen, clutches, bearings, pulleys, shafting, and structural steel trommel supports and housings.

Among the recent sales made by the DORR CYANIDE MACHINERY Co., Denver, are the following: 1 Dorr continuous thickener to El Tigre Mining Co., Yzabal, Mexico; 2 Dorr classifiers and 1 Dorr thickener to the Homestake Mining Co., Lead, South Dakota; 1 classifier to the Emana M'Cubwa Copper Co., Rhodesia, South Africa; 1 classifier to the

Motherlode Mining Co., Sheep Creek, B. C.; 2 classifiers to the Gold Road Mining Co., Kingman, Arizona; 1 classifier to W. B. A. Dingwall, Matehuala, San Luis Potosi, Mexico; 1 thickener to the Vulture Mines Co., Wickenburg, Arizona; 1 classifier and 1 thickener to the Cia. Minera Las Vaca, San Diego, Chile; 2 classifiers to the Tom Reed Gold Mines Co., Kingman, Arizona; 1 classifier to Charles Butters & Co., Ltd., Virginia City, Nevada; 1 classifier and 5 thickeners to the Ophir Gold Mines, Milling & Power Co., Ophir, Colorado; 3 thickeners to the Beek Mining Co., Atlantic City, Wyoming; 4 thickeners to the U. S. Treasury Mining Co., Engle, New Mexico; 4 thickeners to the Blue Flag Mining Co., Victor, Colorado. The last four named companies are installing continuous decantation process of cyaniding.

## Catalogues Received

HAYWARD Co., 50 Church street, New York. Pamphlet No. 590, 'Hayward Buckets and Digging Machinery.' 8 pages. Illustrated. 6 by 9 inches.

GARDNER CRUSHER Co., 566 West 34th street, New York. Catalogue No. 3, 'Gardner Crusher, Disintegrator and Pulverizer.' 24 pages. Illustrated. 4½ by 7½ inches.

SULLIVAN MACHINERY Co., Peoples Gas building, Chicago. 'Mine and Quarry,' June issue. Also Bulletin No. 58-L, covering air-compressor accessories, and Bulletin No. 63-H, on Sullivan iron-clad coal cutters.

FORT WAYNE ELECTRIC WORKS, Fort Wayne, Indiana. Bulletin No. 1139, 'Motor Drives.' 48 pages. Illustrated. 8 by 10½ in. Also Bulletins No. 1136, 1137, 1139, 1140, 3053, and 4515, describing electrical machinery.

INGERSOLL-RAND Co., 11 Broadway, New York. Form No. 8007, 'Little David Pneumatic Drill.' 16 pages. Illustrated. 6 by 9 inches. Also Form No. 5003, 'Radialaxe Air-Driven Coal Cutters.' 20 pages. Illustrated. 6 by 9 inches.

ALLIS-CHALMERS Co., Milwaukee, Wisconsin. Bulletin No. 1630, 'Hydraulic Turbines,' Types FH, FV, and OH. 24 pages. Illustrated. 8 by 10 in. Also Bulletin No. 1802, 'Sampling Machinery and Equipment.' 48 pages. Illustrated. 8 by 10 inches.

COLORADO IRON WORKS Co., Denver, Colorado. Catalogue No. 10-C, 'Advanced Cyanide Practice and Equipment.' 70 pages. Illustrated. Size 6 by 9 inches. The catalogues issued nowadays by many engineering firms are quite as useful as some text-books published; in fact, more so, as they are written as the result of practical experience. The above book, issued by the Colorado Iron Works, may be said to come under this head. The cyanide process is explained in its various applications in the treatment of gold and silver ores, in a concise manner. Two features in the bulletin are the drawings and explanations of the principle of counter-currents, and washing by continuous dilution in cyaniding ores. In the first system, the solution is supposed to take up gold or silver from the pulp of lowest value, while the ore is losing value as it passes down through successive tanks toward the discharge. This is done by agitators and thickeners being alternately placed. In washing by continuous dilution it may be found difficult to keep the percentages of solids and solution to the nicety shown at each successive step in treatment. Useful information is given on tube-mills, pans, filters, and accessories. A few tables are given on tank capacity, rates of flow of water, and slime density relations.

ALUNITE occurs in Colorado, according to a report by E. S. Larsen, of the U. S. Geological Survey (Bull. 530-F.). The mineral is found in San Cristobal quadrangle. The rocks of this region have been greatly altered by volcanic action. The occurrence of the alunite was noted by Mr. Larsen only incidentally to the geologic mapping of the San Cristobal quadrangle, and the few analyses made do not show potash to be present in probable commercial quantities.

## EDITORIAL

**B**UTTE and Park City reports have been finally issued by the United States Geological Survey. It remains now but to complete the Leadville monograph.

**T**HE Senate resolution regarding foreign concessions for American harbors is but the statement in form of what every European country holds in substance. Germany would probably object as strenuously to Denmark ceding England a coaling station on its mainland, as the United States would to the same country ceding Germany a coaling station in the West Indies.

**S**EPARATION of surface from mineral rights in oil lands in Utah is proposed in Senate bill 3045, favorably reported to the House of Representatives at Washington. The proposed act permits entry and patenting of the reserved oil lands in Utah under the homestead and various other laws permitting the taking of agricultural land, but reserves to the United States the oil and gas in the lands. Disposition of these materials is to be subject to future legislation, but anyone acquiring rights under this act will be required to compensate the holder of the surface of the land for all damage due to prospecting or removal of the gas and oil. As at first drawn the bill proposed the same treatment for all reserved oil and gas lands, but as reported to the House its operation is restricted to Utah, in which a special emergency is held to exist.

**M**INE-RESCUE crews are gradually being organized and trained at the metal as well as coal mines in this country. While there is not the danger of gas explosions that exists in coal mines, fires, powder explosions, and bad air all cause conditions under which rescue crews as well as trained first-aid men may be needed. The Goldfield Consolidated, we believe, led the way among Western metal mines in training and equipping a rescue corps. The Portland Gold Mining Company was a close second, and the good examples have now led a number of companies operating on Beacon Hill in the Cripple Creek district, including the El Paso Consolidated, the Gold Dollar, and others to join in a neighborhood station. Equipment has been purchased and men are to be trained so as to be prepared for every emergency. Such movements to increase safety in mining are well worth while and deserve the hearty cooperation of all mine managers, and no part of the work of the Bureau of Mines has deserved more support than that done in focusing attention on the need of this preparation.

**R**UMOR travels fast on a stock exchange, and an announcement is quoted and re-quoted without, at times, any too close effort at verification. In the case of the United Verde Extension Mining Company, discussed by our Boston correspondent July 13, there was apparently a temporary feeling of distrust because it was thought that a deliberate effort had been made to confuse the public and to lead it to assume that participation in the reorganization by Mr. James S. Douglas, involved Phelps, Dodge & Company becoming sponsors for the property. The

original circular letter distributed from the office of the company, contains no such intimation, and the whole mistake was due to the similarity in name and the relationship of Mr. James S. Douglas to Dr. James Douglas. It is hard for the son of a famous man to get out from the shadow of a great name, but in a case such as this it is a penalty Mr. James S. Douglas may well pay gladly. That the plan of organization when thoroughly understood commended itself to the stockholders was shown by the fact that only one minor holder of shares voted against it. We hope that Mr. Douglas' venture in mining may turn out as well as have those of his eminent father.

**L**ABOR conditions are particularly unsatisfactory in New Zealand just at present, and matters may easily get worse. At Waihi, the engine drivers and miners are at loggerheads, and the Waihi and Grand Junction mines and mills have been shut down some ten weeks; nearly 2000 men being out of work. A large district is fast being depopulated. The Federation of Labor, which controls most of the unions in New Zealand, tried to force the enginemmen to join the central union. They would not do so, and consequently the miners stopped work abruptly. The companies concerned met the men in conference, but without result. Apparently about 80 per cent of the men are against the strike, yet none are willing to agitate against it. The mines are filling with water, though at such a slow rate as surprises everybody, especially the miners, and it will be at least twelve weeks before the water reaches the top of No. 10 level in the Waihi mine, and no damage is expected in the stopes. No machinery of any kind is at work, save a dynamo at night. Waihi is a fine little mining district, and the aspect of affairs is disheartening. At Waikino, where the big mill is, and a picturesque little town has sprung up, there is hardly a soul about the place. It may be remarked here that the whole of the Ohinemuri mining district is a prohibited one, as far as the selling of drink is concerned, and has been for about four years now. The strikers are receiving small strike benefits. At Reefton, on the west coast of the South Island, the miners objected to working 'baby' drills, singlehanded, as is done at Waihi and many mines in Australia. They are out on strike, and the Progress, Blackwater, and other small mines are shut down. At the time of writing, the matter was being investigated by a commission, and both sides were determined. There also seems to be great unrest among the coal miners in the South Island, and judging by the stocks of coal stored in Wellington and Auckland, and reports of big storage at other centres of population, a strike is expected. Such a general unrest of labor is not good for a small country, and a strike in one industry is all too apt to spread to others.

### Foreign Trade and Canal Tolls

Panama canal tolls are being much discussed at present as a result of the action of Congress in providing for free passage of American ships, and the protest thereat filed by Great Britain. We print elsewhere a short note on the matter written by Mr. Courtenay De Kalb. The opinion he expresses is one widely held, and it is not too much to say that those who dissent from it, do so regretfully. There is much of sentiment that harks back to the days when the American merchant marine was supreme, and which looks forward hopefully to a return of American ships to the seven seas. There are also, as Mr. De Kalb suggests, substantial advantages from a business point of view in having the aid of our own ships in developing a foreign market for surplus manufactures. Nevertheless, we do not believe that the bill as passed by Congress is a wise measure or that it

is a proper cause for jubilation. We hold in this case with Mr. Roosevelt that the intent of the Hay-Pauncefote treaty was clearly to provide equal treatment to the ships of all nations, including our own, in foreign trade. Any other construction of the treaty impresses us as forced; as a mere shifty quibble over terms. This is the opinion of the man who, probably better than anyone else in the United States Senate, is prepared to judge the matter fairly and without prejudice—Mr. Elihu Root. That distinguished lawyer and ex-Secretary of State knows if anyone does, how the treaty should be interpreted, and in this case at least no cry of 'corporation leaning' can be raised against his judgment. Believing, as we do, that in this matter the good faith of our Government has been solemnly pledged to the world, we cannot express other than profound regret that it should be proposed to violate that pledge. Entirely aside, however, from the moral aspect of the case, which should clearly be sufficient to determine the matter, it is not, we think, good policy to discriminate in this way against foreign shipping. A recent writer in the *Statist* has brought out strongly the fact that England's great growth as a sea power and colonizing nation, while based upon the necessities of her people, was none the less profoundly promoted by the freedom of trade that characterized her march of conquest. Wherever the English flag was raised all men traded on equal terms. It was therefore to the advantage of other nations as well as of Great Britain, that India should become English, and opposition of other nations was stilled. Our own country has embarked upon the opposite policy. When we took Hawaii and the Philippines we erected a tariff wall and extended the coastwise shipping laws to cover the territory. What, therefore, of advantage has it been to neutral nations to have us extend our rule? What, for example, has Germany gained by our conquest of Porto Rico? And if each nation sees in every added conquest by another, only one more bar to her own trade, is it not natural that each should in turn seek to extend her own rule? It is difficult to see any basis in equity for our maintaining a closed door to Japan in the Philippines and Hawaii, and insisting on an open door in Manchuria. The activities of other nations, our own among them, have compelled Germany to take her present disturbing position in international affairs; namely, that every gain of another country can only be permitted on the basis of compensation to her. We are accentuating the tendency toward walled-in rival spheres of trade; the greatest present danger to the world's peace.

Trade should be a mutual affair. We cannot expect to sell to the Orient unless we buy from the Orient. We must 'exchange' goods rather than 'sell' them, taking in return either goods or services. Only if we enter international trade on this broad basis can we expect it to prosper. The handling of our goods may well be payment in service for part of our exports, and whether the bargain be good or bad cannot be determined by general rule. In international commerce it is particularly true that stooping for the nickels of the present, we may lose the dollars of the future. The sharp antagonism of the world, conviction at the bar of judgment of previously friendly nations of having violated treaty obligations, is too heavy a price to pay for an advantage of \$1.25 per ton in carrying charges on a limited part of our foreign trade.

Ship subsidies have been repeatedly proposed and as regularly defeated at Washington. The long record of graft and injustice that has marked government aid to other lines of industry has apparently aroused unconquerable opposition to any such measure. Indirectly the remission of tolls on American shipping passing through the canal is a subsidy; but it is a most unequal one. Under

the proposed conditions a steamer carrying nitrate from Chile to New York, and presumably American products south, would be favored; the same steamer traveling to San Francisco, would be at a disadvantage. On the other hand, trade between San Francisco and the River Platte would be favored at the expense of New York and other Eastern ports. The net effect would be to favor the longer water-haul, and that is understandable if it mean cheaper service. The latter, however, could only come from steamers traveling more miles for less money, rather than receiving more money for the same or less miles, the ordinary result of a ship subsidy. It would seem that if aid is to be given to American ships in foreign trade it would be better frankly to pay a tonnage bonus that would be non-discriminating.

It is a grave question whether subsidies are necessary to the development of American shipping. In that connection it is worth nothing that much of the American trade is carried in foreign vessels that receive no government aid. Further, it is a fact, not generally recognized, that many of these vessels are in reality owned in America. The International Mercantile Marine, while almost entirely under foreign flags, is largely owned in America. The Standard Oil Company, the United States Steel Corporation, and several other American companies have large fleets, run usually under the British flag, but owned by Americans and as devoted to building up American trade as though they flew the stars and stripes. Among independent steamship companies may be mentioned the Robert Dollar Company, with a line of excellent steamers regularly handling freight between Pacific coast ports and the Orient. These boats are not subsidized by England, nor does Norway pay anything toward the running expenses of the boats that bring coal from British Columbia to San Francisco for the Western Fuel Company. In the face of such facts we are far from being convinced that subsidies are as important as are first cost and shipping regulations. On the open seas the world comes into competition and the American shipowner if permitted to buy his steamers on the same terms as his competitor and to run them under the same rules and regulations, seems abundantly able to care for himself. Running into San Francisco from Japan are two lines of steamships, the Toyo Kisen Kaisha and the Pacific Mail Steamship Company. Both run excellent modern boats, manned mainly with English or Scotch officers. The crews of the Japanese boats are, naturally, mainly Japanese; those of the Pacific Mail are largely Chinese. Close and competent observers estimate that the cost of handling freight and passengers on the two lines is practically equal. The Japanese company receives aid from its Government, though the bulk of its business consists of handling American freight to and from China. The American company receives only the ordinary payment for carrying mail. Last year the Toyo Kisen Kaisha paid a 4 per cent dividend. The Pacific Mail Steamship Company showed a profit of a few thousand dollars, but earned no dividend. The reason lies not in the difference in shipping laws or the matter of subsidy, but in the fact that the Japanese company needs only to earn a profit on the cost of its boats in terms of ordinary interest. The American company must do better. It must pay, and does pay, a profit on the cost of the boats, but also it pays tribute to 'the dead hand.' In other words, the Pacific Mail Steamship Company does not own its principal boats, but leases them upon terms that involve payment materially above interest on the investment. When the new boats were built, instead of the company borrowing the necessary money at ruling rates, one of the officers of the concern built the boats and leased them to the company upon terms favorable to himself. It was a typical bit of

American high finance, and failure of this company to pay dividends cannot be used as an argument for financial aid to American shipping. Unfortunately, there is reason to believe that similar conditions underlie other widely advertised 'failures' of American lines.

In the discussion above we have spoken only of the proposed measure as it affects foreign shipping. There are two other phases of the bill which, we believe, are also objectionable, but concerning which there is abundant room for difference of opinion, but for the proposed free tolls for American ships in foreign trade, we can see no justification, and we reiterate our disbelief in the necessity of subsidies and our obligation to the systematic campaign of misrepresentation urged in their behalf which has deceived many honest and patriotic Americans.

### Iron and Steel in Australia

It is announced that the Broken Hill Proprietary Company, Ltd., has bought 200 acres of land near Newcastle, New South Wales, for the purpose of erecting large iron and steel works. The operations of this great concern include its mine, a 2000-ton capacity concentrating mill, acid-making and flotation plants at Broken Hill, and the slime-sintering works a few miles out from there; lime quarries and iron mines; a large blast-furnace plant, a refinery for lead, and a spelter plant costing about \$500,000, at Port Pirie, in South Australia; and coke ovens at Bellambi in New South Wales. The Proprietary is a wealthy company, its reserve and insurance fund totaling some \$1,300,000, which will help to pay for the new works. The time seems propitious for building iron and steel plants in Australia. Great development in railroads and tramways is contemplated and must be pushed, since this country, which is as large as the United States, is deficient in internal communications. Each state is constructing new lines every year, while the Commonwealth Government has just begun a line from Kalgoorlie, in Western Australia, to Port Augusta in South Australia, a distance of 1060 miles. The rails for this line will be imported. Before long this government must also construct the road from Oodnadatta, in South Australia, to Port Darwin and the Northern Territory. Besides the railway requirements, a great deal of iron and steel is and will be used for mining, agriculture, and shipbuilding. At present the importation of iron and steel manufactures of all kinds into Australia is valued at about \$30,000,000 annually. Hence, the entry of the Broken Hill Proprietary Company into this field would seem to be well-timed. For some years past a blast-furnace and rolling mills have been producing pig iron and steel shapes at Lithgow, in New South Wales, the production of the former of good quality has reached over 40,000 tons in one year. Labor troubles have hindered work, but up to June 30, 1914, there is a bonus of \$2.88 per ton payable on all iron produced from Australian ores, which probably will be extended.

In iron ore resources, the Commonwealth is rich. On the Blythe river in Tasmania there is a deposit of 17,000,000 tons; large quantities have been recently found at Yampi Sound, in the northwest of Western Australia at Carcoar, in New South Wales, there are 3,000,000 tons of mixed hematite and limonite averaging 50 to 60% iron; and Cadia, in the same state, about 4,000,000 tons of 50 to 65% iron; while at Iron Knob, in South Australia, there are 20,000,000 tons of 60% ore. This latter deposit is owned by the Broken Hill Proprietary, but up to the present, has only furnished iron for fluxing the lead ore and concentrate in the blast-furnaces at Port Pirie. With the active railroad and shipbuilding era now opening in Australia the new enterprise should do well.

## Metallurgy at Bendigo

By M. W. VON BERNEWITZ

Bendigo, the famous old mining district of Victoria, Australia, has had a bad name in the past for its metallurgical methods, yet any careful student is forced to admit that although plants have been and are out of date, and costs of milling are high, the results are astonishing. I recently spent three strenuous days inspecting mills and discussing treatment with local engineers. I was rewarded. About \$360,000,000 of gold has been produced from the Bendigo field, and it has not been found payable to treat the tailing dumps. It is quite safe to say that the ore from the Bendigo mines will never require any different process from that at present in vogue, yet the plants at work need much alteration to effect cheaper results. The field may be said to be in a transition stage from the old to the modern type of mill; and it is pleasing to note such a movement, especially now that the field has shown good returns on recent exploratory work in the upper levels and sidelines of reef. However much the Bendigo mills are obsolete, they are well kept and clean. The total cost of treatment in the old mills is about 80c. per ton.

It is probably the simplest ore in the world to treat; and is practically similar from each line of lode down to 4000-ft. depth. It mainly consists of a clean white quartz in which the gold occurs in a somewhat coarse form, while it also contains about 2% of arsenical pyrite, which produces some 5% of the total gold output. Nothing but simple treatment is necessary, since amalgamation in boxes and on plates, with a table of some kind, will extract practically everything. As an example of this, one mill may be cited which is crushing ore worth \$12 per ton, and the residue after this treatment is only worth 50c. The residue from other plants runs from 16 to 50c. per ton. In the past, the saving of the pyrite was not as good as it is now, and a characteristic feature of each surface plant is a shed containing canvas tables worked by Chinamen. These metallurgists did fairly well for a time; but not so well now. Their methods will be described later.

About two years ago a syndicate sent engineers to Bendigo with the object of sampling the old tailing heaps, which are as prominent on the landscape as they are at Kalgoorlie. If worth enough, it was proposed to erect a large central plant, transport the tailing by some cheap method, and cyanide it. The quantity was there, but not the quality. Cost of transport would have been fairly high, and the business was dropped. A cyanide plant was erected some time ago, but could not be made to pay. One trouble was the acidity of the sand, due to decomposition of pyrite, and the consequent necessity of using much lime.

From the mines to the mills, the ore is carried by rope-ways, carts, and trucks. The use of rock-crushers is extending, and many mills are provided with a gyratory of about the No. 3 Gates size. At the majority of mills feeding is still done by hand, one man to 10 or 15 stamps. This is one of the costly features of a Bendigo mill. I have heard it stated that a good hand feeder is equal to an automatic machine. To some extent, on certain ores, this may be so; but only under very exceptional conditions. Challenge feeders are used at Bendigo, and several local machines, one of which seems to me to be fearfully clumsy. Save two, every mill visited was of the iron-frame type. In them a row of cast-iron columns or posts carries the cam-shafts and guides, and a row behind carries the driving shaft, which is on a level with the former. The driving shafts are mostly direct-connected with the engine crank and drive the cam-shaft by gear and clutches. Gear of all sizes is used, and there must be a deal of friction from this source.

The mortars of a very old design, being deep for good

amalgamation and having a discharge up to 5 inches. They are built to receive 4, 5, or 6 stamps in each. Cam-shafts carry 10, 12, 15, or 24 cams; in the last case, two being coupled together. Breakage of cam-shafts is rare, as is also breakage of stems. If anybody wishes to see a variety of cams at work, let him go to Bendigo. There are the long-arm type, the separate boss and arms fitted together on the bedpost principle, half cams bolted around shaft, the Spier's dovetailed, and the modern Blanton. All cams of the old style are keyed and show much ingenuity in design, the effort being to secure ease of removal. Dovetailed cams seldom work loose.

The stamps on the field would average 850 lb. weight, with 80 drops of 8 in. per minute. They crush from 2 to 4 tons each per day. The tappets are raised or lowered on a large thread on the stem, and have renewable wearing faces. Each stamp has a separate iron guide. A regular order of drops is attempted, but in a 6-stamp mortar I noticed the two centre ones dropping together, then the outside ones, and last the second pair. Heads, shoes, and dies are made locally, and last up to six months. The speed varies at times. Punched and wire screens from 14 to 40 mesh are used.

It would seem that power on an old-type battery would be high, but one old millman and engineer assured me that his 60 stamps took only 40 hp., or  $\frac{2}{3}$  hp. each. Talking about old batteries reminds me of a fairly recent comparison at Kalgoorlie, where a worn-out battery cost \$1200 in power, against \$500 in a modern mill on the same tonnage, which is rather a difference.

Careful attention is paid to amalgamation. A high percentage is caught in the boxes. For instance, in a lot returning 127 oz., 104 oz. was found in the box. Several short plates, in all up to 12 ft. long, with riffles between, are used. These are invariably kept locked. Berdians and retort furnaces are found in each clean-up plant, some mills having as many as five furnaces to deal with small lots from tributaries or individual mines. The general amalgam retorts as high as 66%, and the average value of the gold is \$19.50 per ounce.

The pyrite averages 2% of the ore, and carries 5% of its value. In the past it has been caught on the Halley percussion table, which mainly consists of a table about 5 by 3 ft., knocked forward by a three-arm cam and back by a flat spring. Its work is fair—one table for 4, 5, or 6 stamps. Most of the batteries now have installed the Phoenix-Weir table, after trials against the Wilfley, Card, and others. Its driving gear and deck are somewhat similar to the Wilfley. One table to 10 stamps is the rule. A small copper plate is fixed to the pyrite discharge of some tables, and collects a little amalgam. In some cases the overflow from the tables flows over blankets, which catch a little more mineral. All concentrate is sold to public works. Another feature of Bendigo mills which crush for the public, are the separate bins of pyrite from each lot, along with the coarse pannings from the boxes. Concentrate averages \$40 per ton.

Two well known works (Leggo's and Edwards') buy concentrate from the various batteries, and I was able to see a section of each plant. The pyrite contains an average of 12% arsenic, and the method in each is to roast, following by cyanidation at Leggo's, and chlorination at the Edwards' plant. In the former works roasting is done in Leggo's patent furnace. This consists of four superimposed hearths, each in itself being a complete furnace with fire-box, feeder, and discharge to push-conveyor. The floors have an area of 60 ft. by 6 ft. 9 in. For rabbling the pyrite there are 16 spindles, worm-driven at 1 r.p.m., with 4 rabbles, one on each floor; 64 in all.

The rabbles are water-cooled. The furnace capacity on concentrate is 30 tons per day, and 100 tons on an ordinary sulphide ore with, say, 4% sulphur. At the Edwards' there is a simplex, and one duplex Edwards' furnace, the latter 79 by 11¾ ft., traveling at about 1½ r.p.m. The hearth has a ⅝-in. fall per foot. There are about 600 ft. of chambers to catch the arsenic. The roasted pyrite

hemp and old rubber, and have three clean water-jets to keep the sand from cutting. Self-priming apparatus is used which is simplicity itself. I was shown plungers that had been in use for years. The batteries only crush a few hundred tons per week, and the plungers last a long time, though they still require some attention.

As regards the elevation of pulp, it is interesting to

CHARING CROSS AND PALL MALL, BENDIGO.

TYPICAL SCENE IN THE BENDIGO GOLDFIELD.

is damped down, screened into vats of 4-ton capacity, fitted with tight lids and a gravel filter. Chlorine is made in an Edwards' semi-rotary generator. The vats are worked in series.

At most of the Bendigo mills the pulp is lifted to ponds by pumps. A few air-lifts are in operation. The elevating of pulp at Bendigo has reached a high stage of development. The pumps are of the Cornish plunger type, with poles up to 16-in. diameter. They are packed with

note that Cornish pumps are used at Bendigo; 3-throw pumps, a few wheels, and bucket-elevators at Kalgoorlie; bucket-elevators at Broken Hill; wheels and bucket-elevators in the Waihi-Paeroa district; and wheels and centrifugal pumps on the Rand.

I should say that the Bendigo ore would yield 75% sand. At Bendigo the Chinaman has had the right, on a royalty basis, of saving what he can out of the pulp from the batteries. His skill in metallurgy is well known. I have

seen it in Borneo and Bendigo, and in the former north-west district of Sambas, among other works, I saw a girl wash off *dulong*s full of gravel with great skill. In the sheds erected near the sand dumps are several tables with blankets or canvas. These catch the fine pyrite, and are disposed of to the pyrite works. Not much is made out of the treatment now. The Chinaman keeps the ponds in order.

When discussing why modern plants are not erected at Bendigo, the usual reply is that they would not do on this ore, where amalgamation is so important, not denying that they would be cheaper to work. A fast-running battery would throw out the gold from the mortars, and the plates would not catch it all. It is argued that one battery had to slow its stamp for this reason, yet, on the other hand, an up-to-date mill is being erected on the Catherine Reef; and a very good mill is at work on the Central Red, White & Blue mine. The residue from the latter is worth only 50c. The argument does not seem to hold, yet there are many opponents of the fast battery. It is largely, perhaps, a matter of experience in amalgamation.

The visitor to Bendigo sees three or four long, unbroken lines of brick stacks and head-gear, and scores of acres of dumps. The head-gear is generally of good design, the legs being made out of pipe, wood, or lattice. At Kalgoorlie, the head wheels are fixed toward the front of the top, and the shaft in the centre of the four legs; while at Bendigo the wheels are fixed in the centre, and the shaft is toward the centre of the two back legs; another example of each district following its own practice. All machinery in use is made in Victoria, either at Bendigo, Castlemaine, or Melbourne. There are Cornish, Lancashire, and water-tube boilers, consuming wood and coal. A great deal of slack coal is bought from the Government mine at Powlett. This costs \$4.08 per ton delivered, as against \$2.04 for wood. Forced draft is necessary at times. Newcastle coal is also burnt.

Hoists are of general good design, being mostly first motion, and some being fitted with Corliss gear. The battery engines are hardly of a highly economical type, although condensers are attached. The suction gas-engine is being introduced slowly, and two 120-hp. Crossleys are at work on the Central Blue, while others are on the Prince of Wales and Nell Gwynne, reducing costs. Engineers are paid \$2.16; feeders, \$1.60; and mill hands \$1.92 per day.

In the table below are summarized the main features of the leading Bendigo mills.

In the Reserve, in the Mall of Bendigo, a bronze statue of the late George Lansell has been erected, and it stands there with a lump of white quartz in its hand, he having been called the 'Quartz King.' The mines controlled by the family produce some \$30,000 per month. Lansell's Bendigo battery of 105 stamps is the largest in the field, and is a custom mill. It is also an old-timer, having been built in 1888. A remarkable feature of the plant is the huge main shaft, level with the cam-shafts, and driving the latter by gear and clutches. It is tapered slightly from the engine end to the far stamps. The New Moon has a 200-hp. Bellis & Morecom set, driving 150-kw. Westinghouse generator. This is for the mine hoists and crushers. There is also a belt-driven generator for two 10-hp. motors, driving pumps, etc. In this mill, after long tests, the Phoenix-Weir table was judged to be the most suitable. The Catherine Reef is about to start a fine new plant, which may be compared to the old one in the table given. As good a saving with the high-speed battery is expected as is now made in the old slow one.

Clarke's public mill, a clean and tidy plant, was quite interesting, and the owner courtesy itself to me, as in fact was everybody I met on my rounds. At this mill were found hand-feeding; mortars with 4 and 6 stamps; 12 cams on a cam-shaft, and one with 24, it being made up of two 12-cam shafts coupled; about five styles of cams; 4-in. discharge; 2¼-ton capacity per stamp; yet the huge dump of tailing worth only 40 to 48 cents per ton. I was deeply interested.

The Central Blue has as good a battery as I have seen, the only faults being that the mill is a little cramped about the crusher, the roof over the stamps is rather low, and the cam-shafts seemed to be too long between the bearings and first stamp. It is a Victorian-built mill, and a joy to watch at work. An aerial tram brings the 800-lb. capacity skips to a No. 3 gyratory crusher, and the broken ore is distributed to the bins by belt. The 20 stamps were crushing 100 tons daily through 180-screen at the time of my visit. About 8 tons of pyrite is collected weekly, and the residue is only worth about 50c. on \$12 ore. The plant is driven by a 120-hp. Crossley suction gas-engine, belt driving the main drive shaft, the power used being from 60 to 80 hp. The cost per ton for power was 10c. A 120-hp. Crossley engine also drives by belt a 10-drill Ingersoll-Rand compressor. Good amalgamation is effected in this fast mill, and the total costs are 40c. per ton, which may be compared to advantage with 80c. in an old-timer.

Copper and Sulphur in Cyanide Solution

By WILL H. COGHILL

In contradistinction to a process\* in which the ready solubility of copper in cyanide solution is an advantage in the extraction of zinc sulphide from the ore, I wish to show a case in which the ready solubility of copper in cyanide makes the commercial extraction of silver from the ore a difficult problem. The results relate to two similar samples which were tested simultaneously. They will be designated as samples A and B, assaying 36.27 and 26.75 oz. silver, respectively. There was less than 1% sulphide minerals and the gangue was a silicate rock. Galena, sphalerite, pyrite, and rhodocrosite were identified. The sulphides contained nearly all the silver; in fact, it was estimated that if it were possible to make a concentrate consisting wholly of sulphides it would assay more than 2000 oz. per ton.

After a number of tests which showed that something in these samples was possessed with an inordinate desire to consume cyanide it was decided to make a long-period air-agitation test, changing the solution frequently, thus preventing fouling and to test the pregnant solution for base metals. The quantities of reagents consumed and silver dissolved are shown in the appended Table I.

Note that the consumption of KCN per ton of ore during

silver was dissolved and this is easily explained by the fact that most of the silver having been previously extracted, there was little left to dissolve. Cannot the decreased consumption of cyanide be explained along the same lines, that is, the cyanide is in very small quantities and is practically all consumed during the first 90 hours?

Table II throws some light on this question. It is the result of the determination of the amount of copper in the samples and in the solutions.

TABLE II

Amount taken in A.T.		Copper in ore, %	Copper in sample, mg.	Copper dissolved, mg.	Copper dissolved, %	Total copper dissolved, %	Total silver dissolved, %

Tailing assay, 3.32 oz. per ton, 87.7% extraction.											

90 hours agitation ranged from 7.2 to 11.6 lb. Note also that the greatest cyanide consumption was during the first six hours and a greater percentage of the silver was dissolved during this period than any subsequent. The large discrepancy between 'total percentage Ag recovered' and percentage extracted as determined by assay of tailing is to be accounted for by the unavoidable losses during transfer of solutions. The assay of tailing is correct and indicates the percentage extracted; however, the figures under 'percentage silver recovered' give a good idea of the rate of dissolution.

In 31, for instance, it is noted that only 5.2% of the

The analysis of the samples shows a quantity of copper (0.29 and 0.21%) that would be considered negligible in most cases, but not so in this; for in 37-41 23.9% of this copper was dissolved. It seems, then, that the suspicion that the cyanide was in small quantities and finally spent itself was correct, though the percentage of total copper dissolved is barely comparable with that of the total silver dissolved.

In order to secure more pregnant solution for further tests, a grinding in cyanide test was made, lasting 48 hr. The tests were each aerated twice. Table III shows the status regarding dissolved copper and silver. The results are nearly identical with those shown in Table II and

\*McGregor. Eng. & Min. Jour., Dec. 2, 1911, p. 1080.

are here recorded to show that the amount of copper dissolved is independent of quantity of solution and method of treatment—that is, whether by air-agitation or grinding in cyanide.

TABLE III

GRINDING IN 4-LB. CYANIDE SOLUTION.

Name.	Ore.	Sol.	Copper in ore, %	Copper in sample, mg.	Copper dissolved, mg.	Copper dissolved, %	Total copper dissolved, %	Total silver dissolved, %
Sample A...	2	8	0.29	169	23.7	0.04	14.0	76.3
Sample B...	2	8	0.21	122	31.6	0.05	26.0	83.3

Table IV, which follows, portrays, I think fairly accurately, the conduct of the cyanide in the test shown in Table III.

TABLE IV

	Sample A.		Sample B.	
KCN as:	Lb. per ton solution.	Per cent.	Lb. per ton solution.	Per cent.
Free cyanide .....	1.30	32.9	1.60	40.6
KCNS .....	1.17	29.6	0.91	23.0
KAgCN <sub>2</sub> .....	0.57	14.4	0.46	11.6
4KCN.Cu <sub>2</sub> CN <sub>2</sub> .....	0.73	18.5	0.97	24.6
Error .....	0.18	4.6	0.01	0.2
Total .....	3.95	100.0	3.95	100.0

The amount of free cyanide remaining was determined in the usual way, with silver nitrate and potassium iodide indicator. The table shows that only 32.9% and 40.6%, respectively, of the cyanide added remained as free cyanide. The KCN as KCNS was determined by the permanganate method for estimation of thiocyanates as outlined by Clennell in 'Chemistry of Cyanide Solutions.' The KCN as KAgCN<sub>2</sub> is an estimation based on the amount of silver dissolved. The copper salt was calculated in the same way. Inspection of the 'error' column shows that all but a very small amount of the KCN is accounted for; but after all, one cannot be sure. And here I wish to point to a paucity of published information. During each of the 52 weeks of the year there are several articles published in our mining magazines alleging to describe cyanide processes. They always begin by stating that the ore is run onto grizzlies, and near the end state the strength of cyanide solution, seldom referring to cyanide losses. If cyanide loss is mentioned, it may possibly be subdivided into physical and chemical, but the reader will have to search a long while to find what constitutes the chemical losses. If the cyanide chemist does not investigate and find the cause of chemical losses, he is either overworked or negligent. If he investigates and does not publish his results, he is not doing his duty to fellow-workers.

In the case of the samples under discussion, it would certainly be unscientific to dope the solution with this and that before finding what salts are present. Clennell has indeed given us two excellent books to aid in such determinations. However, there are yet some uncertainties. I refer to the copper compound. I will quote here from Clennell's 'Cyanide Handbook,' page 80:

"The compound 4KCN.Cu<sub>2</sub>CN<sub>2</sub> is the form in which copper, according to Virgoe, normally exists in cyanide solutions, though Sulman considers that it is more frequently present as sulphocyanide, Cu<sub>2</sub>(SCN)<sub>2</sub>, dissolved in KCN. \* \* \* The reaction (in the presence of an excess of alkali) which, according to the writer's experiments, seems most in accordance with the facts, is as follows:

This indicates a consumption of 3.6 parts KCN for every part of Cu dissolved."

The calculations in Table IV were based on the above statement. Referring to page 112 in the same book, I take the liberty to multiply (a) and (c) by 2 and (d) by 3 for reasons that will be obvious later.

"The natural sulphides of copper are much less readily acted on by cyanide than are the carbonates, or than artificially prepared sulphides, but they gradually dissolve, probably with formation finally of cupric thiocyanate, by some such series of reactions as follows:

The insoluble cuprous thiocyanate and cyanide readily dissolve in excess KCN.

Since the solutions almost invariably contain an excess of alkaline thiocyanate, the further reaction is probably as follows:

Upon adding these equations, the following equation results:

Here it is seen that 8 times 64 parts of copper consumes 16 times 65 parts of KCN, or one part of copper consumes two parts of KCN, which is a much more favorable ratio than the one previously cited, and has further in its favor the decomposition of some of the KCNS that naturally forms in the presence of sulphides.

Using the data which I have derived from Clennell's four equations, Table IV may be recalculated as below:

TABLE V

	Sample A.		Sample B.	
KCN as:	Lb. per ton solution.	Per cent.	Lb. per ton solution.	Per cent.
Free cyanide .....	1.30	32.9	1.60	40.6
KCNS .....	0.76	19.2	0.37	9.4
KAgCN <sub>2</sub> .....	0.57	14.4	0.46	11.6
Cu(CNS) <sub>2</sub> .....	0.41	10.4	0.54	13.7
Unaccounted for .....	0.91	23.1	0.98	24.7
Total .....	3.95	100.0	3.95	100.0

Here two thiocyanates have to be reckoned with instead of one. Taking into account the amount of copper in solution, the KCN as cupric thiocyanate is first calculated and all thiocyanate left over is reckoned as KCNS. The amounts of KCN as Cu(CNS)<sub>2</sub> is 0.41 and 0.54, respectively. An inspection of the formulæ of these two thiocyanates shows that the results of titration are the same whether the sulphur is in KCNS or Cu(CNS)<sub>2</sub>; therefore, to find the amount of KCN as KCNS (left over after satisfying the copper), it is necessary only to take the results from the KCNS column in Table IV, which are 1.17 and 0.91, and subtract from them 0.41 and 0.54, respectively. This gives 0.76 and 0.37. In other words, the quantities under 4KCN.Cu<sub>2</sub>CN<sub>2</sub> vanish, and there are two thiocyanates which are not distinguishable by titration with permanganate. The 'error' is thus increased by the amount of KCN as 4KCN.Cu<sub>2</sub>CN<sub>2</sub>, which has been eliminated, and it seems best to call it 'unaccounted for.'

It is worthy of note that there is less difference in the percentages 'unaccounted for' than there is in the 'error'; these being 4.6% and 0.2% in Table IV and 23.1% and 24.7% in Table V. I cannot explain away such a large percentage under 'unaccounted for'; for, as I have shown, our authority has not stated positively how the copper occurs. The grinding was done in an Abbé sample jar, and since the protective alkalinity did not get below 0.3, certainly no HCN was formed.

A reference to alkalinity suggests another phase of the

investigation that may be of interest. It relates to the acidity of these samples. Naturally the first test made was a half-hour agitation in lime water, to determine acidity. This was found to be sufficient to neutralize 3.6 lb. CaO in each case. It soon developed that this test had failed to reveal the true conditions; that the indicated acidity depended upon the time of treatment and state of comminution. This is shown in Table VI.

TABLE VI  
ACIDITY TEST.

Sample A—Agitation		Strength of solution.			Lime consumed per ton of ore.	
Amount in A.T.		Before	After 2 hr.	After 24 hr.	After 2 hr.	After 24 hr.
Ore	Solution					
Dry crushed.....	1 6	2.0	1.2	1.1	4.8	5.4
Slime .....	1 6	2.0	0.9	0.6	6.6	8.4

The 'dry crushed' was crushed dry in an Abbé jar mill, and was so fine that 85% passed 150-mesh; while the 'slime' was ground wet in the same apparatus until all passed 150-mesh. An attempt was made to find the cause of this accumulating acidity, but lack of time has prevented a thorough investigation. I will say, however, that suspicion rested upon the copper. Much has been written lately about the ready oxidizability of copper; for instance, Durant<sup>2</sup> says: "There are few published records showing that unoxidized copper ores are actually leached in place on a working scale, but such is actually the case, and the fact is that it has been carried on, day in and day out, for over 60 years at a mine barely 300 miles from London."

Then again Bushnell<sup>3</sup> says, regarding the precipitation of copper from mine waters at Butte: "Some of the operators are so fortunate in the situation of their plants that they can cause the water to flow through the tailing heaps of abandoned plants, thereby materially increasing the copper contents of the water."

The air-agitator was therefore put to work and ran five days on a pulp consisting of slime and water. The solution, at the end of this period, instead of revealing copper sulphate and acid, showed that acidity was absolutely nil—another theory exploded. Since the copper mineral in this slimed material resists oxidation, while chalcocite, Cu<sub>2</sub>S, is known to oxidize easily, it seems probable that the copper does not occur as Cu<sub>2</sub>S but in some mineral such as argentiferous tetrahedrite, for instance.

CONCLUSIONS

- 1. Copper, though in very small quantities in the ore, may be a detriment to cyanidation.
- 2. Sulphur, though but a small amount of sulphide be present, may form an appreciable amount of thiocyanates.
- 3. In order to find how much cyanide has been consumed by copper, it does not suffice to make analysis for copper, but the composition of the copper salt must be known. This ratio may be anything between 3.6 to 1 and 2 to 1.
- 4. For a given amount of copper entering the solution, it is more desirable, from the standpoint of cyanide consumption, for it to occur as a sulphide than as an oxide.
- 5. The 30-minute agitation test in lime water does not accurately indicate the acidity of an ore, since the indicated acidity depends upon length of period of treatment and state of comminution of the sample.
- 6. More data should be collected on the subject of chemical losses. This must largely emanate from the ore-testing laboratory for the simple reason that a chemical loss of

much magnitude prohibits treatment on a commercial scale. If interest should be aroused in this subject, it would be but a short time until there would be enough published data to be of aid in devising schemes to overcome chemical losses, thus making many ores available to cyanidation which cannot be so treated at present. The average client is generally reluctant to pay for purely scientific investigation, but the cyanide chemist who will not make a few tests purely for the fun of it, has failed to see the best that is in his profession.

Lead Prices and Production

Under date of August 3, L. Vogelstein & Co. report conditions as below: Except once a year when Government statistics are issued, it is impossible to get a line on the position of this metal, and unless the market itself gives evidence of what is going on, it can only be surmised. There are available, however, statistics of the consumption of other metals (all for six months to June 30, except tin, which is for seven months to July 31):

	1912 (tons).	1911 (tons).	Increase.	
			Tons.	%.
Pig iron ....	14,072,274	11,666,996	2,405,278	17
Spelter .....	159,046	134,902	24,144	18
Copper .....	197,000	168,500	28,500	17
Tin .....	29,400	26,000	3,400	16

From previous experience it is safe to assume that the uniformly increased consumption shown by these figures may be taken for granted also in the case of lead. Previous experience, however, does not warrant the belief that there is or can be so large an increase in production, the entire increase, five years 1907 to 1911 inclusive, amounting to exactly 10%, or 2% per year. On this hypothesis that the consumption of lead is increasing faster than the production, we are constrained to hold a favorable opinion of the metal, especially in view of the large advances which have taken place in other metals while lead is still selling at relatively low prices.

Foreign lead has advanced to £19, equivalent to 4½¢. in American currency. The duty on lead in ore is 1½¢. per pound. The domestic market must therefore rise to at least 5½¢. to be on a parity with the foreign market. European correspondents state that the situation there is entirely sound, and they expect a maintenance of present prices and possibly higher. Hence if a reduction of the tariff here were imminent (which it is not), it would be no menace to present prices of pig lead in this country.

Business in lead has been adversely affected the last year or two by high prices for linseed oil. This difficulty will shortly be remedied if present favorable prospects of the flax crop are realized—in fact, is now being remedied. Lumber which a few years ago cost \$10 per M now costs \$30 per M, and the importance of protecting it has increased accordingly. The prosperity of the farming regions should not be underestimated in this connection. Work hitherto deferred, together with new work, will mean little short of a boom for the lead industry. Advance indications that this period is approaching are already in evidence. Corroding plants are crowded with orders, and other lines, large consumers of lead, such as the electrical industry and the building trades, are fully occupied. It is our opinion that were figures available, they would show a larger increase in the consumption of lead than of any of the other metals referred to above.

THE price of antimony was so low in 1911 that there was little encouragement for American miners to produce the ore unless it contained other valuable metals. The production of secondary antimony as antimony in the United States was 10 short tons; and 2359 tons was recovered in alloys. The output was valued at \$359,040. In 1910 the recovery was 9 and 2770 tons, respectively, valued at \$444,600.

## The Nevada-Douglas Mines

By THOMAS T. READ

The plural number is here used with intention, since the Nevada-Douglas Copper Co., at its properties on the west side of Singatse range, Lyon county, Nevada, is carrying on mining operations for the extraction of both copper ore and gypsum. In addition the copper ore is being mined from two sets of workings, the Ludwig and the Douglas, differing 700 ft. in elevation, which though not differing greatly genetically, yet present many features of contrast that make necessary the employment of diverse methods. As a proper preface to their description it should be said

MAP OF WESTERN NEVADA, SHOWING SITUATION OF NEVADA-DOUGLAS MINES.

that the copper deposits of the Yerington district, in which these mines occur, are replacements in limestone, of which beds of considerable thickness occur in association with masses and dikes of grano-diorite and dikes of porphyry. The orebodies clearly have been produced by igneous emanations and the characteristic garnet zones have been well developed, sometimes at considerable distances from the intrusive. F. L. Ransome has briefly described\* these ore deposits, but since the period of his visit (1908) a large amount of development work had been done and it is to be regretted that no more detailed study, by an equally competent geologist, has been made of this district, which is one of great scientific as well as economic interest. My own visit to the Nevada-Douglas properties was limited to one day, and my data are therefore chiefly based upon 'information and belief'. The broader features of the deposits are, however, discernable by even a brief inspection and I shall therefore attempt to set them forth.

The Douglas orebody is exposed over a surface area of about 20 acres, crowning a hill that rises 800 ft. or more above the level of the railroad track at Ludwig. The exposures of ore on the surface extend away to the southwest,

reaching the railroad at the Casting Copper workings, and also extend a considerable distance to the south. The outcrop is characteristic of the district. The limestone is profusely stained with chrysocolla and malachite and when excavations are made to shallow depths at these points stringers of chalcocite and bornite, admixed with chrysocolla and malachite are found, and sometimes are of such size that by sorting, considerable quantities of rich ore can be taken out. A cross-section of the hill would show a thin leached crust with a thin band of enrichment below it, underlain by orebodies of unknown extent in depth. Mining in this district in the period from 1870 to 1910 was largely restricted to the search for and extraction of such small bodies of rich ore, which would bear the cost of shipment to distant smelters. This zone of rich sulphides is shallow, and is quickly succeeded by a zone in which the primary sulphides have been altered but not enriched, at least to any marked extent. In other words, though chalcocite is present the copper content of the ore is not markedly higher than where chalcopyrite alone is present, the alteration consisting in removal of the iron rather than by additions of copper. The importance of this feature is at once evident. Though the grade of ore near the surface is rather low there is no reason to expect that it will rapidly decline with increase in depth. Beyond a few shallow winzes the Douglas orebody has not been explored beyond a depth of 100 ft. so that it is as yet impossible to confirm this belief by underground study, but the evidence of the winzes, while not conclusive, tends to confirm it. At the level of the railroad track an adit is being driven under the hill, following the garnet zone, and another adit is being driven 150 ft. below the present workings, so that evidence as to persistence in depth will soon be available.

The evidence disclosed in a few openings in this orebody is not conclusive because of the irregular nature of the deposit. It may be briefly and fairly accurately described by saying that the mineralized area resembles that culinary product known as 'marble cake'. The normal dip to the limestone is 50 to 60° southeast, but varies locally because of the disturbance by intrusion and by faulting. The portions of the limestone which were naturally more open textured and porous, or which have been rendered so, have been permeated by the mineralizing solutions and contain ore, while the denser portions of the limestone are remarkably fresh and unaltered. In a recent report made to the company, E. P. Jennings estimates that, in the area of about four acres which has been quite thoroughly explored to a depth of 100 ft. by adits and raises, about one-third the total volume is workable ore, averaging 4.7% copper. If the limit of profit could be reduced to 2% a much larger proportion of the ore would be minable and if profitable methods of handling so low-grade material can be devised it is quite possible that very large orebodies may be developed.

As already pointed out, the orebody shows great variation from point to point, and for a thorough study of it a large number of samples should be examined. For this I had neither time nor opportunity, but a fairly typical specimen of almost unoxidized material, taken from the main adit, proved, when studied in thin section, to be an aggregate of grains of garnet in which the sulphides, chalcopyrite, and pyrite, serve as the cementing material. The sulphides are everywhere bordered by a bluish black alteration product that could not be identified with certainty. In more altered material from the same level this change had progressed until the original sulphides only existed as a central core or as scattered islets in the black mass. Here some of the dark material was evidently chalcocite and bornite, but much of it could not be identified, and it is at least doubtful whether more than a part of it consists of

\*Bull. 380, U. S. Geol. Survey.

such rich copper sulphides, as its abundance would in that case indicate a copper content much higher than is shown by analysis. This appearance might perhaps be presented by a small quantity of copper sulphides disseminated through limonite. The light-colored minerals have also decomposed, giving the sand specimen somewhat the appearance of a kaolinized syenite. C. P. Berkey, in a report made to the company, has suggested that this altered material is possibly saussurite, but with the thick sections and antiquated microscope which were the only available materials for study, I was unable to do more than perceive the more obvious characteristics. The chrysocolla and malachite that are so much in evidence in the hand specimen of surface material almost disappear in the thin section, which shows chiefly garnet, light colored silicates, probably epidote and saussurite, and a colorless mineral which appeared to be quartz. The ores evidently present such diverse characters that generalization from a few specimens is impossible, and it is to be hoped that a thorough study may be undertaken in the near future.

The Ludwig mine is a short distance to the northwest of

600 tons of ore, averaging 5.4% copper, is available at this point. The ore available throughout the remainder of the mine is given as 290,000 tons, containing 5.4% copper. It may be said generally that the orebodies in the Ludwig are thoroughly oxidized to the 400-ft. level, and are largely oxidized to the 600-ft. level, and even below. The depth to which oxidation here extends is doubtless due to the fact that a fair amount of water is present in the Ludwig, while the Douglas orebody is dry, the surface waters having penetrated to a depth of only a few feet.

A short distance west of the orebody a large deposit of gypsum occurs and has been quarried to a depth of about 50 ft. A cross-cut from the shaft on the 400-ft. level cuts this deposit, but on penetrating it for a short distance the gypsum changes to anhydrite. This deposit has been described in some detail by A. F. Rogers,<sup>1</sup> whose conclusions have been criticized by J. C. Jones.<sup>2</sup> According to Rogers the bed was deposited as anhydrite, and later converted to gypsum by hydration. Jones believes the gypsum to have been deposited in the form of a bed, later converted into anhydrite by the igneous intrusions; and finally again con-

LUDWIG SHAFT.

DOUGLAS ADIT.

the Douglas and 700 ft. below it. The orebody is of great interest, both because it represents the nearest approach to an ordinary vein to be found in the district, and because there is much difference of opinion as to its character. Mr. Ransome, in the paper already cited, says: "The Ludwig deposit differs from those on the east side of the range in the fact that it fills a fissure." Mr. Jennings, in a report to the company, describes it as a contact deposit lying between the limestone and the underlying metamorphic rocks. The impression obtained in the few hours I was able to spend underground was that the ore occurred in crush-zones within the limestone. At one place on the seventh level the orebody has been cross-cut for 90 ft. without finding any hanging wall, though at this point the grade of the ore decreases to 1 or 2% copper and shows less oxidation as the distance on the hanging wall side increases.

The former owners of this mine had developed it to the 400-ft. level and had stoped out the richer portions of the deposit. Stopping is now in progress over the entire width of the orebody in these old workings, the average grade of the ore mined being about 5%. At the south end of the sixth level, faulting has occurred and the orebody appears to be totally leached, while on the seventh level development work now in progress indicates that the top of a zone of enrichment has been reached, sulphide ores assaying as high as 7 to 12% copper being present. More water is found at this point than elsewhere in the mine, but the total amount is small, though the seventh level is below the ground-water level. The management estimates that 180,-

verted to gypsum by surface waters. The latter conception is perhaps the more probable one. This deposit must be counted as one of the Nevada-Douglas mines, since the gypsum is now being mined in an open-cut and shipped at the rate of 75 tons per day. Shipments are made to the Western Gypsum Co., of Reno, which prepares and markets the gypsum. Since the raw gypsum contains about 24% water of crystallization, the calcination plant will eventually be moved to the mine, no doubt, to avoid payment of freight upon the water content.

There are many mines which present geological features of great interest, but certainly few which present so great a diversity of mineral deposits, both in character and kind. The great scientific as well as an undoubted economic interest of the deposits of the Nevada-Douglas mines would seem to justify more elaborate study than they have yet received.

COPPER production increased in Utah from 127,597,072 lb. in 1910 to 146,960,827 lb. in 1911, an increase of 19,363,755 lb., according to the U. S. Geological Survey. The Bingham district produced 129,995,865 lb. of copper in 1911, against 113,725,280 lb. in 1910, 92,560,340 in 1909, 71,155,740 lb. in 1908, and 45,431,964 lb. in 1907. The Tintic district yielded 10,922,154 lb. in 1911, against 8,993,036 lb. in 1910, an increase of 1,929,118 lb. The Park City district, in Summit and Wasatch counties, produced 1,281,190 lb. in 1911, against 1,423,629 lb. in 1910.

## Saving Time in the Laboratory

By HAROLD FRENCH

Motion study is not as a rule applied to the men who labor in the laboratories. As long as their results are satisfactory and their determinations are accurately performed, they are generally left to their own resources and devices. In most laboratories work often piles up, especially during a rush season, and it is then that the man with a system wins out. All experienced technical men have increased their efficiency in many ways, but the beginner will profit most, who learns to eliminate unnecessary motions in the manipulation of his apparatus. To develop system is essential.

Many an assayer is blamed unjustly for not accomplishing more work in a given space of time, when, as a matter of fact, the fault may largely lie with the designer of his workshop. Either it was constructed in the first place on too extensive a scale, or the quarters are cramped. If the management can be induced to make necessary changes, the assayer may save himself future unpleasant occurrences by convincing his employer that there will be real economy in the long run by remodeling the plant. A pipe from a distant boiler may convey steam to heat water for washing apparatus and otherwise facilitate operations. Also, the steam may be partly condensed to supply necessary distilled water for analytical work. Simple fixtures may be installed at low cost; for example, pine or oak lockers for storing equipment and keeping it clean. The tops of such furnishings may serve a double purpose as tables. Shelves should always be placed as near as possible to the centre of operations where reagents may be kept in ready reach of the worker.

The placing of assay furnaces in an adjoining room is always desirable in order to keep the laboratory where wet work is being done as free as possible from dirt, obnoxious fumes, and heat, and prevent the ever possible contamination or unintentional salting of an assay with metallic particles. However, the room where fusions are performed may be situated at too remote a distance, and the taking of even a thousand needless steps each day may consume a quarter of an hour of valuable time. Therefore, it is a good plan to have a pane or two of glass in the door or wall adjacent, so that the operator may watch his work in two rooms at once. Wherever gas is available, it is preferable to other fuel for muffle fusions and cupellations, while crude oil is far more economical and convenient than coke in heating crucible furnaces. While gasoline is satisfactory in firing smaller furnaces, petroleum or its heavier distillates are much less expensive. In many assay-offices the heat of the furnaces may be utilized to warm water for washing purposes or distilling water for laboratory purposes whenever more extensive facilities are not available.

There is probably no line of work where parsimony in the purchase of necessary supplies is more wasteful than in laboratory practice. Cheap apparatus is often the most costly, when unsatisfactory results are the sequence of securing flimsy porcelain or glassware, inferior crucibles, or impure reagents. If a laboratory is deemed a necessary adjunct to a metallurgical plant or a mine, the assayer has a right to insist upon being supplied with essential equipment and having it purchased from a reliable dealer in technical goods. There is no more niggardly retrenchment than the restriction of an assayer or chemist to a small hand mortar and pestle for the preparation of his samples, and yet there are many men today who are compelled to putter away in this old-fashioned manner, wasting an hour or more of their time each day at about the least skilled labor they can perform. This is not an argument against necessary manual work in a laboratory, but it is based on personal observation of offices where the assayers were tediously pounding away hour after hour at a small hand mortar while their work was piling up. All

the while the preparation of samples could have been performed in less than one-tenth the time by an electrically-driven crusher and pulverizer. All business-like laboratories are fully equipped with such up-to-date labor-saving devices, but there are still many places where even the purchases of a bucking-plate and muller would enable the assayer to accomplish much more work in a day. It would hardly seem necessary to emphasize the fact that an assayer should have every facility to enable him to crush a sufficiently large sample of ore and pulverize it fine enough to obtain a fair average of its metallic contents, and yet there is many a timorous technical man who fears to offend his official auditors by asking for a labor-saving device, because he believes that his employer will think he is getting lazy. As long as he is making a racket with his ear-racking mortar, he thinks his active life will be longer. Not that this is the psychology of scientific workers, but, unfortunately, in some establishments the spirit of penury affects the efficiency of operatives.

Hardly too much can be said about keeping a laboratory clean. In designing a building for this purpose it is well to place the windows so that dust may not be driven in by prevailing winds, while the fumes of smelter or other furnaces should be excluded as much as possible. Scales should always be kept in an inner room with a tight-fitting swinging door. Leather or rubber strips should be placed on the tops, sides, and bottoms of doors, so as to keep out objectionable currents of air. A tight-fitting case should cover each set of scales when not actually in use. The time necessary for removing the case just before weighing is more than compensated by the less frequent cleaning of the scales. A cement floor may be kept clean most readily, and wherever careful work is being done, slabs of slate or soapstone may be laid to good advantage. In some places silicate of soda may be spread as an acid-proof glaze over cement, if the friction upon the floor is not too heavy. Considerable economy in the use of reagents may be effected by keeping them in convenient bottles of uniform strength. Where a few drops of an acid or an alkaline solution or an indicator are required in wet work, the use of a small dropping-bottle will prove very handy. For a number of years I have had several such bottles within arm's reach. They contained from 50 to 100 cubic centimetres, and had curved spouts tapering to a tiny jet. They frequently enabled me to obtain a required reaction with what the late and beloved Professor Rising used to term "the merest fraction of a drop." These little dropping-bottles would not only pay for themselves in a short time in the economy of time alone, but they would avoid the occasional excessive use of reagents.

Nothing is more important than keeping track of samples from their receipt to their final accounting. All samples should be carefully kept in paper bags classified as far as possible according to their character or the place from which they came. Small labels may be affixed to beakers and other apparatus wherever there is any possibility of confusion. This is sometimes necessary when two or more workers are using the same apparatus and interfering with each other. Cupel trays are most useful in enforcing the habit of placing cupels in a regular and unmistakable order. It is also helpful to keep a ruled slate beside the muffle and trace the progress of scorifiers or cupels by checking the same with chalk. Occasional errors or accidents which happen in laboratory work may be greatly minimized by the adoption of such safeguards until the beginner develops a systematic procedure all his own, which in time becomes so habitual that his subconscious self can be depended upon to perform certain practices with unerring results. Under the pressure of a plethora of work, this second nature must be depended upon to keep in constant mind a large number of determinations or assays at the same time. Therefore, a memory trained by systematic methods will enable the chemist to keep track of each piece of work according to its stage of development.

Test-tubes with bottoms enabling them to stand in a vertical position are far more convenient than the old familiar form, except when it is necessary to heat them over a flame. Therefore, it is desirable to have both kinds of tubes. There is also a new style of reagent bottle which is equipped with a cover that when laid down holds the stopper tilted upward at an angle so as to prevent its coming in contact with contaminating substances. It also greatly facilitates the keeping of the laboratory work-tables more clean and less stained. Volumetric methods are usually preferred to fire assays or gravimetric determinations, whenever practicable, on account of their greater rapidity. And yet there are many who still stick to the more tedious and cumbersome processes for reasons best known to themselves and not to their employers.

I have found the microscope a useful adjunct to laboratory work in connection with a metallurgical plant. Frequently there would be brought samples of materials for assaying, regarding which it was only necessary to know whether they contained enough precious metal to warrant reduction in a furnace or treatment with acids. Placing a comminuted sample on a slide under the lens, it was

possible to see at a glance whether the material contained precious metal. As a result of these preliminary examinations with the microscope the unnecessary performance of hundreds of assays was obviated each year, and the chemist was free to do more important work. Occasionally, in the assaying of bullion, it happens that small particles of ferric oxide from the iron molds become mechanically mixed with the silver-gold button. Nitric acid does not attack the oxide, and after the final washing of the residual gold it remains with the metal as an impurity. It happened that certain assay returns were suspiciously high, and in doing some umpire work I placed the finely-divided gold under a microscope and was able to show that particles of ferric oxide had been weighed with the gold. Subsequent treatment with a few drops of hydrochloric acid, after annealing the imperfectly parted residue, removed the ferric oxide, and accurate and concordant returns were obtained. Whenever in doubt about the homogeneity of such particles, it is a good plan to use the microscope. A good instrument will pay for itself many times over in the saving of labor and materials, which on certain kinds of analytical work will prove to be unnecessary.

## Standard Consolidated Mine at Bodie

\*The property was examined with reference to the following points: the advisability of unwatering the Standard, or the Lent shafts, and continuing development at or below the 1200-ft. level; the desirability of acquiring the mines of the Southern Consolidated M. Co.; and the present condition of the mines and property of the Standard Consolidated M. Company.

In the Bodie ground the Fortuna vein is the mother lode of that portion of the district, and this vein was developed down to the 1200-ft. level. The lower levels are now completely under water which stands at 740 ft. from the collar of the Standard shaft, equal to 251 ft. in the Lent shaft. Examination of the 700-ft. level of the Standard shaft shows that many of the veins which were present in the upper workings have pinched out, and only the Fortuna vein has been productive. Below this level former development was unproductive. When the Lent shaft was in operation some twenty-five years ago, about 800,000 gal. of water was handled per day. In order to unwater and prospect this shaft at greater depth it would be necessary to provide heavy pumping equipment, a large hoist, buildings, and to retimber the shaft, as all buildings and equipment have been removed. In the Standard shaft, maps and records show that all levels below 700 ft. were also unprofitable, and in many cases veinless.

The workings of the Southern Consolidated Mining Co. and the assay-plans made by W. H. Landers in 1908 were examined. The Red Cloud shaft is said to be 800 ft. deep. At present water stands at about 490 ft. from the collar. The Noonday shaft is in poor condition, but can be reached on the 500-ft. level by a cross-cut 2400 ft. long from the 450-ft. level of the Red Cloud. The veins of these mines show a decided falling off in the value of the contents at a depth of 400 to 500 ft. from the surface. Based on the sampling and assaying done by Mr. Landers, there is not sufficient pay-ore in sight to warrant the payment of any serious cash consideration for the property, but it would be to the interest of both companies to mine the ore and treat it in the mill and cyanide plant of the Standard Consolidated on some royalty basis.

At present the claims of the Standard company cover a territory approximately 4000 ft. square. It holds a network of veins, a few of them over 2 ft. wide, but most of them narrower, often 6 to 10 in. wide. These veins become impoverished at 400 to 500-ft. vertical depth. The wide veins were exhausted years ago. Only the narrow

seams are left, and many of these are unprofitable, and the others scattered over a wide area connected by long cross-cuts which made their development and mining very costly. Former managers have reported from year to year that the orebodies were practically exhausted, and that no reserves could be maintained. By acquiring adjoining claims and by mining remnants of orebodies in the upper levels, the mine and mill have been kept in operation. The annual reports issued by the company have shown a decreasing tonnage, and an increasing cost for development, and they also show that the value of the ore treated at the present time is much lower than in former years. In the year ended February 28, 1912, an unusual amount of development resulted in a production of about one-half the tonnage produced in earlier years, and the ore was mined at an actual loss, as shown by the following figures from the annual report, based on 8798 tons of ore mined, milled, and cyanided:

	Per ton.	Total.
Mining, including development.....	\$12.67	\$111,510.50
Milling .....	2.02	17,780.19
Cyaniding from mine, 8798 tons, and 15,917 tons of tailing slime.....	2.63	65,046.35
Administration and general expense..	1.16	28,608.04
Total cost .....	\$18.48	\$222,945.08

Against this cost the average value of the ore was \$14.74 per ton, and from this \$6.07 per ton was saved by amalgamation and \$7.19 by cyanide treatment, giving a total yield from the ore of \$13.26 per ton, as against a cost of \$18.48. The resulting loss was offset by the yield from the 15,917 tons of tailing slime cyanide, which amounted to \$7.46 per ton. The total output from the mill and cyanide plant was \$235,476.81, giving a profit for the year's operation of \$12,531.73. The amount of tailing remaining to be treated is estimated at 12,000 tons, and three-quarters of this amount will be exhausted by the close of the present season in November. The grade of ore treated at present is even lower than in the preceding year, and with the decreasing stock of tailing, the slight profit shown from last year's operations will soon be changed into a loss. The present ore reserves amount to only a few hundred tons, and while small orebodies may be discovered in the future, it is advisable to change the working of the mine into a leasing system as soon as possible. The company work should be reduced to a minimum. The Nevada claim on the crest of Standard hill is under option and should be purchased and explored from the 200-ft. level of the Standard shaft. The company has undeveloped water-power rights, and a timber tract of 480 acres which should prove valuable.

\*Abstract of report made by Thomas H. Leggett and Fred Hellmann to the Standard Consolidated Mining Co. on July 18, 1912.

# Assessment of Mining Properties

By C. E. JARVIS

\*I have divided mining property into four classes, namely, mining locations, patented quartz claims undeveloped, valuable patent claims temporarily closed, and producing quartz mines.

Mining locations, with no improvement, are not assessable. Such is my opinion under the present revenue laws. If the person who has a location is willing to pay a tax on a small valuation, I accept it. The improvements on a location, I always assess. In both instances, I collect it as a personal tax, as the improvements will hold; but when I make an assessment on a mining location without improvements, and the owner or claimant thereof refuses to pay the tax, claiming that he does the lawful assessment work of \$100 per year in development, there is no certain procedure. The assessor may seize the property, advertise it for sale, and sell it accordingly to the highest bidder. But the purchaser cannot be given a good, clear title, for the owner has none from the Government. To remedy this defect, I advise that legislation should be enacted that would place a small valuation upon a location, say \$100. If the owner refuses to pay the tax, he will forfeit all right to his location, and some other locator will have a chance to locate and develop the claim. It is well known that the proper assessment work is not always done, especially so when some locators have many claims, which remain in their possession for many years undeveloped. Under the present law I do not think the location privileges without tax add in the least to the development of the mining industry. The man with a good claim rarely refuses to pay a just tax.

All patented quartz claims situated on the Mother Lode or main lode, I value for assessment purposes at \$500, while on claims on spur lodes I place a value of \$250.

In the case of valuable patent claims temporarily closed, I find it sometimes difficult to place a valuation; the conditions in each case require study. The improvements and machinery on this class of property are next to valueless; no great amount can be placed upon the equipment; the value lies in the claim. Some of the properties have a bright past, and there is no apparent reason for discontinuing operations, unless it is due to fire or juggling of the stock. On investigation I often find the owners refuse a large purchase price, and if it be so I gradually increase the assessment each year, which not only stimulates the sale of the mine, but often makes the owners commence active operations. When this has been done, I immediately reduce the assessment to that on a developing property, and thus I try to encourage making each a paying mine.

In one instance I have a claim assessed for \$100,000 which is not operating and has no improvements; but it has a prosperous past, some \$17,000,000 having been extracted. Deep mining in Amador county demonstrates the value of this property, and I have raised the assessment from \$50,000 to \$100,000 in the last five years.

With regard to producing quartz mines, after some study I have adopted the following method, which in most instances has raised valuations, although it has not always been satisfactory to the mine-owners. I ask the mine superintendent for a statement of the operating expenses and the gold output of the mine from March 1 back to March 1 of the preceding year. This statement is not always rendered, and if not, I must make an arbitrary assessment. If the statement received shows no net earnings, I assess all the improvements at 50% of their cost, while upon the claim I place a value that I think will encourage further development.

If the mine is earning a net profit, I assess all the improvements at 50% of their cost. The quartz mill on

the property I assess at \$500 per stamp. For example, an 80-stamp mill would be assessed \$40,000. If the mine shows a net earning of \$100,000, I simply multiply it by 125%, which makes a value of \$125,000 upon the claim alone. Adding to this the improvements, hoists, mill, and unspecified property, I have the full value of the property for county assessment purposes. I claim this is a just way of assessing the producing property; it is only assessed on what it has produced the year before; it is not speculative, and no fictitious stock value enters into the appraisal. The only question likely to be raised is whether the factor used is correct. I shall be glad to argue that point if anyone challenges it. I think the method is fair and just to all concerned. It could also be used with success upon copper, coal, and other mining properties. For dredging, I think the factor should be much larger, for as a rule this class of mining destroys much valuable land that, if not upturned, would produce untold future revenue.

I think it will not come amiss at this time to voice my sentiments upon the franchise tax of mines, in favor of the mining counties in which the mines are situated. I believe they should pay a small annual license tax to the state only. The franchise tax on production, I am convinced, should go to the counties in which the mines are situated, for there is being exhausted a local resource year by year, and when it is exhausted the tax finally falls excessively upon the other class of taxpayers.

The mines are nearly always in a rough country. In all of these mountain counties the land values are small, the communities will never be as prosperous as in the more favored counties where land values are high, and as a consequence mining counties have a high tax rate. Many acres are in forest reserves and therefore not taxable. Under present laws a mine pays about 7½% of its gross receipts in taxes, if it meets all the requirements, such as local taxes, the federal corporation income tax, license tax, state franchise tax, accident insurance, and employers' liability insurance, besides furnishing physician and hospital privileges, for accidents are numerous. This makes a large burden for a speculative property to bear.

In conclusion, I am a strong advocate of a bullion tax on mines, and I trust some state legislation will be enacted to that end. This paper is a written expression of my own personal views, which have been formed by actual experience in the Assessor's office in the county of Amador, whose chief resource is quartz mining. The Kennedy, the deepest gold mine in the United States, with a vertical shaft of 3550 ft., is in this county. Amador county has produced since 1849 over \$100,000,000 in gold. At the present time, after 60 years of continuous operations, it leads all mining counties in the state of California in the production of gold from quartz mining. The pioneer miner thus justly christened the main lode in the state the 'Mother Lode.'

## Mineral Production of Japan

In the report of the Department of Agriculture and Commerce of July 20 is given the quantities of the principal mineral products of Japan for the first five months of 1912. An increase of 6.8% in the gold production is shown, as compared with the same period of 1911, 11.1% in silver, 8.5% in copper, 12.9% in coal, and 8% in sulphur. There were decreases of 6.1% in iron and 6.4% in petroleum. The output for May, and the total since the beginning of the year, is given below, the figures having been recalculated and reduced to Western measures:

	May.	Year to date.
Gold, ounces .....	1,035	55,500
Silver, ounces .....	402,310	1,921,700
Copper, pounds .....	9,459,250	49,199,380
Iron, long tons.....	49,200	231,400
Coal, long tons.....	1,456,377	7,038,077
Petroleum, gallons .....	6,756,080	22,165,760
Sulphur, long tons.....	3,850	16,000

\*Abstract of a paper read before the County Assessors Association of California.

## Shaft-Sinking Reversed

The Nowata Lead & Zinc Co., operating on the Baker estate at Duenweg in the Joplin district of Missouri, has started the raising of another shaft, a big saving in costs and time having resulted from the raising of the first shaft excavated in this manner. The work is described in the local papers as below.

H. Correll, manager for the company, undertook the work, after having received bids for the sinking of the shaft by contract. The lowest contract bid received was \$15.50 per foot for a shaft 5 by 7 ft. in the clear, put down to a depth of 210 ft. This would have meant an expenditure of \$3255. The raising was purely an experiment, this being the first instance of the kind in the Missouri-Kansas-Oklahoma district where a shaft has been driven from the bottom up instead of from the top down. Although many unforeseen difficulties arose which can be remedied in subsequent operations of a similar nature, the aggregate cost of the shaft was only \$1237.58, or \$6.06 per foot.

A 6-in. drill-hole was at the point where the company desired to sink a new shaft. Mr. Correll used the hole as a medium through which a 5/8-in. cable could be passed, to support a working platform at the lower end. At the top, near the drill-hole opening, was stationed a hoist, which was operated so little of the time that an expenditure of 50c. per day for natural gas for fuel defrayed the cost. As this was a minimum flat rate, it was in excess of what would have been charged had only the gas really used been paid for. The drill-hole extended into a drift; the distance from the surface to the roof of the drift where the drill-hole broke through being 210 ft. The cable passed over a pulley in a derrick and thence to the hoist.

At the lower end the cable was attached to a specially constructed platform, built of heavy 2 by 4-in. and 4 by 4-in. oak lumber, the size of the platform being 4 ft. 8 in. by 6 ft. 8 in., thus leaving 2 in. in the clear all around when the platform was hoisted into the shaft. The aggregate weight of the platform, operators, and equipment was 800 lb., divided as follows: stoping drill, 110 lb.; steel, 50 lb.; two operators, 300 lb.; platform, 340 pounds.

Starting the shaft in the roof of the drift was much the same as starting in solid ground at the surface. The 5 by 7-ft. space was marked out, with the drill-hole as its centre, and the work of shooting down the rock was started. A hook permitted the cable to be detached from the platform; thus when shots were fired the platform was lowered to the floor of the drift and pulled to a point of safety to be out of the way of falling rock, while the detached cable was hoisted out in order that it might not be damaged by the blast.

From the time the first round of shots was placed in the roof of the drift until the shaft was completed, cribbing included, 52 eight-hour shifts were required. This was about a third of the time usually required for sinking a shaft of similar dimensions. In raising the shaft, 14 holes were driven to a depth of 5 ft. in the rock. Six of these corresponded to the ordinary sump holes used in sinking a shaft from the top down, while 8 corresponded to the cut holes, 4 of these being driven near the corner and 4 along the edges, midway between the corner holes. Each hole was loaded with four sticks of dynamite, a total of 56 sticks for one charge. Forty per cent dynamite was used. During the work on the first 100 ft., the shots were fired from below, the electrical shot-firer being stationed in the drift. During the remainder of the work the shots were fired from the surface. A signal cord down the drill-hole enabled the operators to signal to the hoistman.

The 18 ft. of surface soil was shot down at a single blast, the drill-hole being plugged at the bottom and loaded with dynamite. The result of the blast was an opening more than large enough to accommodate an ordinary mine-

tub, and in this tub workmen were lowered and the edges blasted out and trimmed. It was this final step that Mr. Correll considers his one big mistake. He believes matters could have been expedited by first sinking the shaft from the surface down to the hard limestone, then beginning the raise. As it was, an enormous mass of clay and gumbo was shot into the drifts when the surface was blasted down, and this became a sticky mass following a heavy rain. It was almost impossible to remove it, and as a result, much valuable time was lost.

This method, when available, has many advantages over the usual methods. The question of drainage is solved. Ordinarily in shaft-sinking, the necessity of removing the pumps before each blast, or the necessity of at least covering them with heavy timbers, is of the greatest importance. Repairs are constantly being made in the pumps as the result of damage from the shots. Water is invariably rising in the sump, and the workmen have an unsanitary place in which to toil. As virtually all of the larger mines of the district frequently use from one to half a dozen extra shafts, exclusive of the mill shaft, and as the underground workings usually connect in this district, the method is widely applicable.

The cost, \$1273.58, includes the fuel, wages, powder, and timbering; every feature, in fact, of the work; it even includes the purchase price of the stoping drill, \$135. It does not include the cost of sinking the 6-in. drill-hole, which was already down. If it had been necessary to sink such a hole, the added cost would have been 80c. per foot, including the casing, meaning a total of \$168 to be added to the figures already given.

At all times the ventilation was good, as the fumes quickly lifted through the drill-hole. In this respect the method is even better than the methods of raising employed in many Western mines where cribbing is built to hold the working platforms. In such cases the air may become foul at the highest point of operation.

## Power at the Alaska Treadwell Mine

The Westinghouse-Parsons steam-turbine plant is now in operation at the mine on Douglas island, Alaska. The hydro-electric power-plant is at the mouth of Sheep creek on the mainland. It consists of two 1900-hp. single overhung Pelton water wheels, direct-connected to two 1000-kw., 3-phase, 60-cycle, 2300-volt General Electric generators. This pressure is stepped up to 22,000 volts, transmitted nine miles to Treadwell, and distributed at 2300 volts. Another plant is being constructed at Nugget creek, 14 miles from Treadwell, and also on the mainland.

For the purpose of hoisting and distributing all the ore from the Alaska Treadwell, Mexican, and 700-Ft. Claim mines, it has been decided to construct a central hoisting and crushing plant. The main shaft of the 700-Ft. Claim will be enlarged and deepened, and the plant so constructed as to utilize this shaft for hoisting from the above mines. A steel head-frame and crusher house will be erected, the latter to contain two No. 12 Gates crushers. The broken ore from these will pass through two 14 by 5-ft. diameter revolving screens, the oversize going to four No. 6 Gates crushers, while the undersize and the crusher product will be delivered to concrete storage-bins by belt-conveyors. The whole crushing plant will be built on concrete foundations, separate from the head-frame. Electric locomotives will distribute the ore to the different mills. Electric power will be used everywhere except at the main hoist. This engine is capable of hoisting 5000 tons of ore in 20 hr. from a depth of 3500 ft. All the above-mentioned work is well under way.

ZINC production of Nevada was 3,548,032 lb., valued at \$202,238, in 1911, against 2,707,071 lb., valued at \$146,182, in 1910, according to the U. S. Geological Survey. This was almost equally divided between a lead-zinc ore and a true zinc ore. Concentrate contained 210,257 lb. and crude ore 3,337,775 pounds.

## Handling Gravel in Siberia

By C. W. PURINGTON

\*In discussion of Mr. Leon Perret's† recent contribution to the literature of methods of handling gold and platinum gravels, I propose to offer a few suggestions based on my own experience. Mr. Perret lays great stress on the operation of stripping overburden, and on the economy achieved by the simple methods of effecting this operation by means of horses and carts, taken in conjunction with hand shoveling. Now I had the good fortune to witness this same operation on the river Iss, some 30 miles below the scene of Mr. Perret's operations, and under conditions, I may say, practically the same, in the summer of the year 1898, some 14 years ago. I am entirely willing to accept Mr. Perret's figures as to the cost of this work; his statement that the cost of such work is from 14 to 28 kopeks per cu. yd. is believed to be correct. In order to arrive at something a little more definite, I will take the average of these figures and say it is 21 kopeks per cu. yd. Even taking the lowest figure, 14 kopeks, it will be seen later that this cost can be lowered by mechanical means. Mr. Perret states as a maximum amount of stripping which he has to deal with in one season, and presumably on one creek, a quantity of 400,000 cu. yd., bank measurement. This amount piled up on the bank would make, say, 500,000 cu. yd. measurement. From Mr. Perret's accompanying statements it is evident that this volume represents the stripping from two operations, and that a volume of from 250,000 to 300,000 cu. yd. will represent the average amount of stripping from each excavation during one season. In other words, each excavation will represent an area 1000 yd. long, by 100 yd. wide, by from 2 to 3 yd. deep, underneath which lies the pay-gravel. It is not easy to know just the dimensions of the cuts which Mr. Perret has to deal with, but I am assuming the hardest conditions for mechanical stripping. If the overburden is twice as deep and half as wide, the conditions for mechanical stripping become easier. Now assume, as I believe to be correct, that the mass of overburden is in section 1 yd. of peat, underlain by from 1 to 2 yd. of sticky clay, and that the mass is to all intents and purposes a dry one, the water having been led off by drain ditches.

From my experience in the use of the drag-line excavator in East Siberia, on the very property which Mr. Perret refers to as the Ohotsky Co. (Okhotsk Gold Mining Co.), I am prepared to maintain that an excavator of the correct description and proportions will greatly reduce Mr. Perret's cost in stripping overburden from the platinum-bearing gravel of the Shouvaloff property.

Before I proceed any further I should like to say a word concerning the indiscriminate use of the word *excavator*, as applied to machines which have been taken into Siberia for placer mining work. Those mentioned by Mr. Perret are, as I happen to know, in every case too small and of a design unfitted for the work for which they are intended. A steam-shovel of good design is fitted for a certain type of mining work, as in handling ore which has been previously broken by shooting, for example, in the porphyry copper mines of Utah, or at Rio Tinto, Spain. It is not fitted, except in very unusual cases, for placer work or any part of the operations connected with placer work. I do not know of any successful placer mine in the world today which uses one. They were formerly used at Cape Nome to a limited extent, but, so far as I know, their use has been entirely given up. The difficulty is exactly what Mr. Perret points out: the system of using tracks and cars for disposing of the material excavated is impracticable for handling material at the low cost required, and it has not sufficient mobility for placer work. The Okhotsk company had two

steam-shovels, one of which I must assume is the one referred to by Mr. Perret, when I examined the property in 1907, and they were without exception the poorest steam-shovels I have ever seen. As they stood they appeared to be of no use for any conceivable purpose. They were dismantled, and one of the engines with boiler was afterward used to run an electric light plant and the other to operate a derrick. Now, if the steam-shovel is of no use on a Siberian placer mine, what form of excavator is of use?

By reference to the following description of a machine used on the Kolehan (Okhotsk) property a general idea of the drag-line type of excavator may be obtained. This one has a 60-ft. boom and is used for the purpose of mining tailing to recover the gold content, and not for stripping. For stripping in the case here assumed, the next size larger machine is recommended, with 100-ft. boom. This machine is operated by one engineer and one fireman, assisted by

two track-layers and one wood-packer. No other permanent men are needed about the machine, but one or two extra men are from time to time needed in making water connections for boiler supply, for making repairs, etc. The machine digs material from a depth of from 0 to 30 ft. below the track, in a radius of 100 ft. from the centre of the rail circle, and stacks the material dug at any desired point within the same radius, and to a height of 20 ft. above the track. It will handle 2000 cu. yd. of average Siberian overburden in 24 hours, or, say, an average of 50,000 cu. yd. per month, allowing for stops to lay track, shift the position of the machine, make water connections, etc. The excavator is of the rail-circle type, the lower carrying frame being itself mounted on trucks, which run on 90-lb. rails. The hoisting cable runs over a head sheave at the outer end of the structural steel 100-ft. boom, and connects with the rigid bale of the bucket of 2 cu. yd. capacity. The pulling cable, winding on the second drum of the double-drum hoisting engine, is attached to the chain-bale of the bucket and also connected with a short compensating cable, which passes over a small sheave and is attached at the other end to the frontal hood of the bucket. By means of the ingenious arrangement the operator can suspend or balance

\*Bull. Inst. Min. & Metallurgy.

†'Gold and Platinum Alluvial Deposits in Russia,' read before the Inst. Min. & Met. See *Mining and Scientific Press*, June 22, 1912.

the bucket in any position. In addition to the throttle, the operator has only two small levers to attend to, which, through the medium of a Westinghouse air control, actuate the two engines, while the brakes are operated by pedals. The bucket is dropped to the ground or into the cut, then dragged toward the machine, filling as it drags. It is generally equipped with manganese steel teeth. After filling, it is hoisted, and the excavator, by means of either rope or geared swing, actuated by the small swinging engine, is swung through an arc until the full bucket is over the desired position in the spoil-bank, when the load of  $1\frac{1}{2}$  or 2 cu. yd. is dumped by letting up on the drag or pulling line.

One man handles the hoisting and swinging engines and controls the entire operation. Russian operators have been trained to run these machines, and to handle as much dirt on a shift as trained imported operators. A fireman who also acts as oiler is the only other man allowed on the machine. Two track-layers are necessary, who work intermittently. The machine works backward, and when ready for a move, after working out one section of the cut, the track-layers are called on to remove the track couplings. The machine lifts a section of track in front and deposits it in position in the rear. When the track is connected the operator digs the teeth of the bucket into the ground behind and pulls the excavator 10 to 15 ft. back. The total operation of changing track and moving consumes only five to seven minutes. The machine is now ready for a new cut. It must be remembered that the bucket can be successfully dumped only in a position vertically below the head sheave, although a certain amount of leeway is allowed by giving it a swing outward. Its range of attack in the cut itself is greater, as the bucket can be swung out 15 to 20 ft. from the vertical, after the manner of casting with a fish-line. It can also dig at any point inside the vertical up to 20 ft. away from the front of the machine. The drag-line excavator is, in fact, the most mobile of all types of mechanical excavators, and the ingenious contrivance of the compensating cable on the bucket is primarily the secret of its efficiency and adaptability. It was a development of the experience of two Chicago contractors, Messrs. Page and Schnabel.

As to actual trials of the efficiency and cost of a machine of this type, I beg to call attention to my account in the *Mining and Scientific Press*, February 4 and 11, 1911, 'Sluicing at the Kolchan Mines, East Siberia.' In this paper the operation of one of the 60-ft. boom machines in mining tailing is fully described. To summarize briefly: the results obtained with this machine from August 12 to October 10, 1910, inclusive, the machine ran for 597 hours, being held up the rest of the time on account of the lack of sluicing water. Had it been engaged in stripping, there is no reason why it could not have been run 22 hours per day. The amount of gravel handled was 35,000 cu. yd., an average of 60 cu. yd. per working hour, and digging to an average depth below the track of 27 ft. and frequently running only one-half capacity, so as not to over-tax the capacity of the sluice into which the gravel was dumped. The working cost of excavating was under 20 kopeks (11c.) per cu. yd. on the small yardage implied, which cost would have been cut at least 25% had the machine not been handicapped by lack of sluicing water.

From the experience of this excavator, and from work of the same type of machine in building a levee along the Mississippi river, where costs do not ordinarily exceed 5c. per cubic yard, there can be no question that for stripping overburden from comparatively narrow pay-channels they will compete with hand labor at any price and under all but most exceptional conditions. Not only in Siberia will their use become extended, but in view of the present interest in the tin alluvials of Northern Nigeria, they should be considered as regards their application to that country.

Judging from the cost of the Kolchan installation on the property of the Orsk Goldfields, Ltd. (above referred to), and the cost of operating the plant, the following is a con-

servative estimate of what the cost would be for a 100-ft. boom machine used on stripping work in the Urals:

First cost at Chicago, 100-ft. boom drag-line excavator	
with necessary spares .....	£4000
Freight to Ural (100 tons) .....	1000
Duty .....	2000
Erection .....	1000
Total first cost .....	£8000

#### OPERATING COST

	Rs.	Rs.
Day shift—		
1 foreign chief operator (first year) .....	20	
1 fireman at 2 rubles .....	2	
3 men at 2 rubles each .....	6	
		28
Night shift—		
1 operator at 6 rubles .....	6	
1 fireman at 2 rubles .....	2	
3 men at 2 rubles each .....	6	
		14
Extra labor .....		8
Total labor per day .....		50
For 200 days .....		10,000
Fuel, 10 cords woods per day, at 2 rubles for		
200 days .....		4,000
Supplies: oil, wire cable, bolts, track repairs,		
carbide, waste, etc. ....		1,000
Annual depreciation and repairs, and allowance		
for overhead charges .....		12,000
Total annual operating cost .....		27,000

On the basis of handling 300,000 cu. yd. per season, which is the duty required of it in the case assumed, the cost will be less than 10 kopeks per cubic yard. It is, of course, assumed that several years' work for the excavator are in sight, otherwise its installation would not be warranted.

That these excavators are strongly made and good for several seasons in Siberia is proved by the case of the one at Kolchan, which is now being used for the third season. Their uses are manifold, and include road-making, a very important function in Siberia. The excavator can also be used as a derrick and a pile-driver. In the case above I have assumed that stripping on the Shouvaloff estate is advisable, the pay-gravel being handled by washing plants of the Russian type. I am not at all sure that this style of washing is advisable on Ural placers, but do not propose to take issue with Mr. Perret on the subject at this time. I would call attention, however, to the floating washing plant which is now being used on the Pokrovsky mine of the Kolchan property, in connection with which the drag-line excavator is being used. The marked success which this plant had last season, handling material which may best be described as a clay bank with a small admixture of stones, suggests that many Siberian argillaceous gravels which have hitherto been handled by the *chasha* and the well known hand methods, may be amenable to treatment by some form of floating plant equipped with log washer, screens, tables, and tailing stacker.

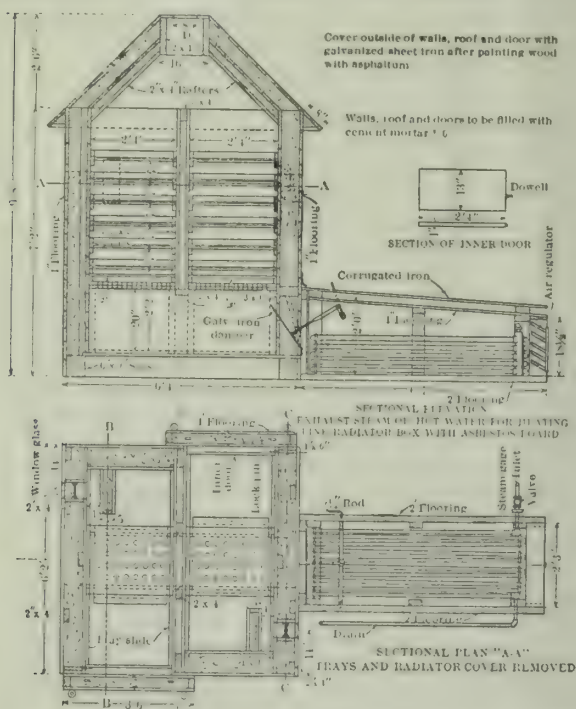

LEAD production in Idaho in 1911 was 272,556,525 lb., valued at \$12,265,044, against 228,258,839 lb., valued at \$10,043,389, in 1910, an increase of over 40,000,000 lb., and was greater than the record production of 1905, according to the U. S. Geological Survey. Crude ore shipped to smelters contained 68,978,613 lb., and concentrate, largely from Shoshone county, 203,577,912 lb. The production of Blaine county decreased 579,421 lb., while Lemhi county showed an increase of 10,328,448 lb. and Shoshone county 35,078,967 lb. The Yreka district, with a yield of 118,725,981 lb., had the largest production in Shoshone county and in the state. The lead output of the Leland district was 84,084,662 lb., and that of the Hunter district was 45,879,504 pounds.

## Magazines and Thaw-Houses For Explosives.

A report upon the above subject (Technical Paper No. 18) has just been issued by the U. S. Bureau of Mines. The authors, Clarence Hall and S. P. Howell, present the advanced practice abroad and in the United States on the use of material for the construction of magazines and thaw-houses, and strongly recommend the use of a lean cement mortar consisting of 6 parts of sand and 1 part of cement as the material to be used in the walls, roof, and doors of these buildings in order that the explosives within them may be properly protected, also in order that life and adjacent property may not be jeopardized when magazines and thaw-houses are constructed the proper distances from other buildings.

In order that the explosives in magazines may be protected, they must be guarded against bullets, fire, lightning, and unlawful entry. Different fireproof materials were experimented with to determine their resistance to the

PLAN AND SECTION OF BUREAU OF MINES CEMENT-MORTAR THAW-HOUSE.

penetration of rifle bullets. Sand offered some advantages, but was rejected because it would eventually flow out on the floor of the magazine through the cracks in the walls and could not be depended upon to remain in the structure permanently; moreover, gritty materials of any kind are objectionable on the floor of a magazine. Mineral wool overcame this objection, but had little value as a medium for resisting the penetration of rifle bullets. Therefore, in order to overcome the objectionable features of sand, portland cement was mixed with it in order to form a lean cement mortar and thus cause the sand to be retained within the walls of the magazine and still be friable enough to crumble readily under a blow. Tests to determine these two features were so satisfactory that a magazine having this cement mortar as a filling was constructed by the Bureau of Mines at a cost of \$400 and having a capacity of 20,000 to 30,000 pounds. A working drawing showing the dimensions and necessary sections are included in the publication. The means provided for ventilation in the magazine of the Bureau of Mines has been found to be adequate, and conditions are favorable for the storage of explosives in respect to their keeping qualities.

The cement mortar construction is effective in resisting

the penetration of rifle bullets, and owing to its friable nature offers an additional advantage for the reason that, in the event of an explosion in or near the magazine, the large masses of material would not be projected over the surrounding country. The galvanized-iron covering is fire-resisting and at the same time it serves as an excellent medium for protection against lightning when the four corners of the building are properly grounded with metal rods.

The method of selecting a magazine site is emphasized and suggestions made. The permissible distance which must obtain between magazines and other structures in England, Prussia, Austria, Italy, Massachusetts, and also the proposed American table of distances, are contained in a table. The proper method of thawing explosives in either small or large quantities, and a suitable method of transporting them to the place where they are to be used is described in this paper. A temperature not exceeding 90°F. is recommended in thawing explosives. In all cases explosives must be protected against moisture and high temperatures, and for this reason thawing explosives by placing them before a fire or near a boiler or on steam-pipes or by putting them in hot water is condemned.

## Panama Canal Tolls

By COURTENAY DE KALB

Our Government has faced a crisis and has not flinched. The sentiment of the American people has been expressed by its representatives in Congress assembled, and Europe now perceives that we are not to be driven by diplomatic threats to abandon our natural advantage from the possession of a trans-Isthmian water-way, as we were once before cowed into servilely repealing the law which granted a rebate of 10% from the duties applying on goods imported in American bottoms. After this we may hope for a maritime policy conceived in the old-time American spirit, calculated to give us a merchant marine that shall extend our markets for manufactures throughout the world. Nothing else that we can do can so surely maintain healthy economic conditions and a high wage-scale; nothing else can so surely allay political discontent as the augmented prosperity which this will bring. It is a wholly different matter to attempt to market the products of our labor through the resident agents of foreign ship-owners and to market them through our agents in foreign parts representing home-owned ships. As our shipping is now conducted the foreigner exploits us; by a change of flag we would exploit the foreigner—wherein lies both a distinction and a difference. The refusal of the Senate to strike out the provision from the Panama Canal bill conceding free toll to ships flying the stars and stripes comes with a refreshing sound like a new declaration of independence.

GOLD production in 1911 in Nevada, according to the U. S. Geological Survey, was valued at \$18,193,397, a decrease of \$685,467. There were increases in gold in several districts, including Manhattan, but large decreases in National and Goldfield. Of the gold output, 10,181.05 fine ounces came from placers largely in the Round Mountain and Manhattan districts, in Nye county, 847,124.81 oz. from silicious ores, 21,847.27 oz. from copper ores, 895.66 oz. from lead ores, and small amounts from zinc, copper-lead, and lead-zinc ores. Silicious ores yielded over 96% of the entire gold production. From bullion in gold and silver mills was recovered 729,252.33 fine ounces, concentrate produced 81,097.61 fine ounces, and crude ore shipped to smelters contained 59,569.92 fine ounces. The leading county in production of gold was Esmeralda, which yielded \$11,198,602, mostly from the Goldfield district. Nye county produced \$3,617,276, of which the Tonopah mines yielded \$2,366,495. The Comstock mines of Storey county produced \$977,349 in gold, against \$502,843 in 1910. More than half of the total value of the state's output of precious metals is that of gold.

Granby Mines

\*The Hidden Creek mines, owned and operated by the Granby Consolidated M. & S. Co., are situated in the eastern foothills of the Burniston range of mountains, which rise to an elevation of 5710 ft., and at this point separate Portland canal from Observatory inlet. The name of the bay has just been officially changed from Goose to Granby bay.

The rock formation in which the orebodies occur may be best described as an argillaceous schist; it has been subject to considerable alteration, and in some places the fissile structure of the argillaceous bands has disappeared and the rock appears to be massive. The orebodies are cut by intrusive dikes, but these have no influence on the nature of the ore, nor on its commercial value.

The ore consists for the most part of massive iron pyrite, with some pyrrhotite, chalcopyrite, and a little bornite, carrying small quantities of gold and silver. In some portions of the orebodies both iron and copper pyrite occur in a quartz gangue, while lime and a little alumina can be found associated with the ore at most points. The amount of gold and silver varies with the copper content of the ore; with 2% copper these together equal about \$1 per ton, and increase in about the same proportion as the copper content advances.

Two main orebodies have been proved on the property; both appear to dip to the west, or toward the main range of mountains. Sufficient exploration has not yet been done to definitely determine the extent or nature of these deposits. At present the eastern orebody, known as No. 1, looks as if it would prove to be a large lens; it has been proved for a length of over 700 ft. in a north and south

\*From a report by D. G. Forbes in the Annual Report of the Minister of Mines for British Columbia, 1911.

direction, and its width, with both the northern and southern ends of the workings still in ore, is not less than 180 ft. The No. 2 or western orebody appears to be in the form of a chimney, roughly 500 ft. diam., but, like No. 1, its limits have not been definitely determined.

A considerable amount of open-cut work has been done on the surface of both orebodies, at an elevation of from 600 to 900 ft. above sea-level, and several short adits have been driven. This work definitely proved the existence of large bodies of ore, but was of little value for economic mining or in determining the value of the ore; it was therefore decided to drive a working adit into the hill, at an elevation of 530 ft. above sea-level, to cut both deposits.

Diamond-drills have been extensively used in prospecting, and where the drill-holes have afterward been intersected by underground workings, the assay values have corresponded as nearly as could be expected with the results obtained from the drill-holes.

At present it is not possible to give complete and exact estimates to the ore in sight in the mine and its value, but it may be safely stated that there is available for extraction above the 530-ft. level not less than 4,500,000 tons of ore, containing 1.8% copper and a combined value of \$1 in gold and silver. The management also states that it has sufficient 4 to 5% ore in sight that could be sent to customs smelter, to more than repay the expenditure on the property, in the event of a smelter not being erected. No ore has been shipped by the present company.

Sufficient water-power for all purposes is available for the greater part of the year, but an auxiliary steam-plant will be required during the winter months, for the creeks, being glacial, run low for several months in winter. Sufficient timber for mining purposes can be obtained in the neighborhood, but, being all spruce and hemlock, it makes poor fuel, and coal will be probably used for the steam-plant.

Metal Production in New Mexico

The value of the mine output of gold, silver, copper, lead, and zinc in New Mexico in 1911, according to Charles W. Henderson, of the U. S. Geological Survey, was \$2,704,843, as against \$2,691,080 in 1910, an increase for 1911 of \$13,763. The production of gold showed an increase of \$280,384 in value, and the output of silver one of \$262,153 in value. The output of copper showed a decrease of \$78,897 in value, lead \$56,637, and zinc \$393,240 in value. Details are given in the table below.

221,882 oz.; these two counties combined yielded 98% of the total silver produced.

The copper output of the state came almost entirely from Grant county, chiefly from Santa Rita, Hanover, and Lordsburg, the county yield being 3,918,928 lb., or 97% of the total yield. The output from Grant county was 485,466 lb. less than in 1910. Other decreases were in Otero and Socorro counties. Copper has always been an important metal in New Mexico, the recorded output from 1845 to 1911 having been 96,380,203 lb. For 1912 and for many years to come, copper will no doubt surpass in value the present total output of New Mexico, through

<sup>a</sup> Includes placer production.

Socorro county, chiefly from the silicious ore mines at Mogollon, yielded \$534,253 in gold, or 70% of the total state yield. There were also increased gold yields in Colfax, Grant, Luna, and Sierra counties, chiefly from silicious and copper ores. Placer gold amounted to \$18,714, as against \$26,094 in 1910. Of the silver yield, Socorro county, chiefly from the Mogollon district, produced 1,109,945 fine ounces, or 82% of the state yield. Grant county, chiefly from silicious, copper, and lead ores, furnished

the operations of the Chino Copper C., at Santa Rita, which was treating 3000 tons per day of 2.24% copper ore early in 1912, and will have its 5000-ton mill completed during 1912.

Of the lead production, the Magdalena district, Socorro county, produced the greater part, with an output of 2,123,039 lb.; Grant county yielded 694,247 lb. Concentrate contained 1,562,768 lb. of lead, and crude ore sent to smelters, 1,403,454 pounds.

## Special Correspondence

### NEW YORK

**MARKET CONTINUES LISTLESS.—CALUMET & ARIZONA ACQUIRES PROPERTY IN GLOBE.—DIVIDENDS OF COBALT MINES.**

The report of the Copper Producers' Association, published this week, found a market so deadly dull as to be far beyond giving any attention to the small increase shown in accumulated stocks of metals. The tickers in New York's financial districts are ordinarily the ganglia of the stock market's nervous system; but the market is nerveless now; the whirl of the ticker falls on empty space. The apathy that prevails includes all lines of business. Bond brokers report that there is 'nothing doing.' Dealers in outside securities can neither buy nor sell. In mining shares such activity as exists is the result of campaigns carried on for the purpose of distribution; that is to say, it is altogether a sellers' market. Copper metal has been at a standstill for ten days, with the price quoted at 17 $\frac{3}{4}$ c. per lb. Copper shares have been equally without incident. Copper stocks increased in July from 44,335,004 lb. to 50,280,421 lb., an increase of practically 6,000,000 lb. Total consumption for the month was 131,215,712 lb., so that the copper surplus, as of record, may now be considered a negligible quantity, equivalent to but little more than a ten-days supply. The fortnightly reports covering copper statistics in England and on the Continent show an increase in the visible supply on July 31, as compared with June 30, of a little more than 7,500,000 lb. The bear raid made in June is said to have killed the speculative activity in London. Comparisons showing the situation month by month are hardly adequate, but when it is noted that the domestic surplus has decreased \*87,500,000 lb. since one year ago, and the foreign visible supply shrunk more than 51,000,000 lb., the outward betterment of the copper metal situation is made plain. However, it is worthy of especial note that the July production of copper of 137,161,129 lb. is the largest recorded since the organization of the Producers' Association. No market movement covering a term of years ever demonstrated more plainly the contrary attitude of the outside public. Three and a half years ago, when the copper surplus was piling up, and some large undertakings, since assured of success, were being planned, the general public was enthusiastically following copper shares. Later talk was heard of a gigantic copper merger, said to have progressed so far as to have had its stock certificates all printed, and the public was expectantly watching for developments. Today the copper merger is an intangible fact; the surplus is gone, production is well in hand, the metal market as high as it can be put without curtailing consumption, and the public looks on and twirls its thumbs. Utah Copper shows a quarterly production of more than 28,000,000 lb. turned out at an average cost of 8.12c. per pound, and net earnings of \$2,622,699; more than \$6 per share, against its present dividend rate of \$3. If one adds the earnings of the Bingham & Garfield railway, and the company's interest in the total earnings of Nevada Consolidated, the quarter shows net revenue of better than three million dollars. It is true Utah returns about 5% per annum on its present market price, but it is not disbursing half of its earnings. The point is not so much the price level of Utah Copper as the attitude of public indifference toward a property proved to be so tremendous and full of possibilities for years to come. The newer properties, such as Miami, Ray, and Chino, are ignored to a like degree, though they represent all in all better combinations of possibilities, safety, and long life than the mining industry has ever before been able to offer in this country.

The Alpha Copper Co., of New Jersey, is once more to change hands; this time by reason of foreclosure pro-

ceedings brought in New Jersey by the Bankers Trust Co. of New York. The Calumet & Arizona Mining Co. is following a movement that is general just now in buying additional properties. The purchase of the Cobre-Verde marks the advent of the Calumet & Arizona in the Globe, Arizona, field. The new purchase was made for \$500,000, and at the same time it is stated that in addition to the 81 claims so purchased, options were taken on several blocks of mineral ground, and the Calumet & Arizona will probably be an important factor in the Globe district from this time on.

The Butte & Superior market has shown a considerable decline, and from its present position would appear to be on an investment basis. The entire mill is completed, and will have a capacity of 1500 tons per day. It will not be operated as a whole, however, until a new hoisting engine is placed. It is stated now that the controversy between the Clark interests and Butte & Superior is not to be considered as a serious matter. It is expected that within a short time Hayden, Stone & Co. will be making a public offering of the shares in the new organization, which has taken up some ground around the Butte & Superior property. A special meeting of the stockholders of the El Paso Consolidated G. M. Co. is called for September 10, 1912, to authorize increase of par value of the shares from \$1 to \$5 per share, thereby reducing the outstanding number of shares from 2,500,000 to 500,000.

Some of the Cobalt properties are continuing to make splendid showings. Kerr Lake is paying a 5% dividend and with this paid, will have returned to the shareholders nearly 140% on the capitalization of the company. The Kerr Lake property is pretty well out of high-grade ore, but will probably continue as a dividend payer for some time to come. The Timiskaming & Hudson Bay has a dividend record that stands unchallenged, in that it has returned to its stockholders 21,100% on its \$7761 issued capital. This year it has paid five dividends each of 300%. The small group of local people who own the Timiskaming & Hudson Bay have been made independent by the development of this concern. The King Edward, at one time one of the favorites of the market operators in Cobalt shares, is to hold a special meeting August 1 at Portland, Maine, to act on a proposal to lease the Watts property and equipment on a royalty basis. The Watts mine is the principal property controlled by the King Edward. The latter was one of the biggest of the market disappointments in the Cobalt list.

### LONDON

**A NEW YUKON DREDGING COMPANY.—SIBERIAN GOLD COMPANIES.—RESTORATION OF PLANT OF TROITSK GOLD-FIELDS.**

The shares of the Granville Mining Co. have this week been placed on the London Stock Exchange. The company was formed in August 1911 to acquire a large number of gold gravel properties on the Indian river and its tributaries, from 15 to 25 miles southeast of Dawson, Yukon Territory. It takes its name from the settlement of Granville, situated at the junction of Dominion and Gold Run creeks. The promoters were A. N. C. Treadgold, H. C. Hoover, and A. Chester Beatty. The share capital amounts to £1,400,000 which was paid as purchase price, and there are £90,000 debentures. Of the latter, £440,000 have been recently issued, and of the funds thus raised, £300,000 is being devoted to the financing of the Canadian Klondike Co., usually known as Boyle's Concession. In return, the Granville company receives \$1,500,000 debentures of the Canadian Klondike Co., together with 29% of its share capital. The Granville has the option for three years to convert the debentures into 20% of the share capital of the Canadian Klondike, and it is announced that this option will be exercised. With the money thus provided by the Granville company, the Canadian Klondike will build two more powerful dredges with

16-cu. ft. buckets. The policy pursued by the capitalists interested in Klondike during the past few years has been to consolidate the properties on a large scale and to work the gravels continuously, instead of picking the best streaks, as was the only method possible for the small man. The first consolidation was the Yukon Gold Co., which owns large tracts on Bonanza and Hunker creeks. The Canadian Klondike Co. owns the property chiefly along the Klondike valley in the near vicinity of Dawson. For some years a single dredge with 7-cu. ft. buckets was used, and at the end of 1910 a large dredge with 16-cu. ft. buckets was built. The profit during 1911 was £45,000. It is estimated that the property contains 100,000,000 cu. yd. of proved gravel averaging 10d. per yard, and that the cost should not be more than 2½d. per yard. There is also a similar amount of gravel not fully prospected, of which one-half is taken as profitable. The Granville company owns property estimated to contain 600,000,000 cu. yd., of which one-half averages 15d. per yard. The company also owns a hydro-electric power station of 10,000 hp., operated by a subsidiary company, and a highly profitable contract has been made with the

DRAG-LINE EXCAVATOR, ORSK GOLDFIELDS.

Yukon Gold Co. for the supply of power. The most interesting information recently published relates to the method that makes it possible to treat these gravels by dredges. Hitherto much of the gravel has been permanently frozen and resort had to be made to steam thawing and other similar devices. It was found, however, that if the overlying deposit of peat and moss was stripped and the earth laid bare to the summer sun, the gravel would be gradually thawed. The stripping may be done mechanically, or by drainage and burning. The gravel on the higher ground is to be hydraulicked. The Granville company is now preparing its property for treatment, and should be producing gold in 1914; in the meantime it will be receiving a substantial income from its holdings in the Canadian Klondike company.

The progress of mining operations in Siberia continues to take a fair share of the attention of London speculators. This week the ventures of the Siberian Proprietary, namely, the Orsk and Troitsk companies, have been prominently before the public. Unfortunately, neither of these has as yet arrived at prosperity, although they both promise future returns. The Orsk Goldfields was formed in 1906 to acquire gold mines in the province of Orenburg in the southern Ural region, but as these proved valueless, a gold gravel property near Nikolaievsk, on the Okhotsk sea in eastern Siberia, was acquired. A stacker-scow was first erected on the Pokrovsky claim, and subsequently a dredge was ordered from New York. The delivery of the latter was delayed by a collision outside of New York harbor, and it was not finally put into commission until the end of October 1911. Various distinguished American engineers have been in charge, namely, C. W. Purington, D'Arcy Weatherbe, and C. H. Munro. W. H. Langan is now the manager. The Pokrovsky plant was in

operation from May 14 to October 18 last year, and extracted gold worth £24,155 from 88,654 cu. yd. of gravel. The dredge ran intermittently from October 25 to December 5, extracting gold worth £2830 from 47,089 cu. yd. of gravel. The total yield was therefore £26,985. The operating cost, administration charges, and winter up-keep amounted to £11,835, the royalty paid was £5921, depreciation £3845, expenses in London £3157; these expenses together with small items reduced the profit to £1557. The Pokrovsky plant resumed operations on May 23 of this year and the dredge on May 18. During 1911, 80,000 additional priority shares of £1 each were subscribed, in order to restore the finances of the company to a sound position after the catastrophe to the dredge and the delay in its erection.

As regards the Troitsk Goldfields, after early disasters Hooper, Speak & Co. were asked to undertake the reorganization and rehabilitation of the enterprise. A new treatment plant consisting of Chilean mills and cyanide vats was erected by H. C. Bayldon, the local partner of the firm. The new mill started in August 1909, and it was described by Mr. Bayldon in a paper read before the Institution of Mining and Metallurgy. Unfortunately, operations were suspended by a fire in the main shaft on May 12, 1911. The timbering was entirely burned to a depth of 260 ft., and seriously damaged to 500 ft.; the shaft caved for 30 ft. at the top; the shaft buildings and hoist were destroyed, and the pumps and compressors damaged. The mill was stopped on June 13, after all the available ore on the surface had been treated. The damage has now been made good. The mine has been unwatered to 500 ft. (the depth of the main shaft is 802 ft.); the shaft has been timbered from 100 ft. to 430 ft., and the top 100 ft. lined with reinforced concrete. Development is being actively pushed and it is intended to resume milling in September. During the time the mine and mill were in operation from the beginning of 1911 to the occurrence of the fire, 15,533 short tons of ore was raised, yielding 4277 oz. gold by amalgamation, 767 oz. by cyaniding sand, and 274 oz. by cyaniding concentrate. The slime is at present being impounded, 5319 tons being stored in this way during the period under review; the total amount awaiting treatment is 63,000 tons averaging 2 dwt. The slime-treatment plant is in course of erection. The ore reserve is calculated at 39,850 tons averaging 7.85 dwt. A report by Mr. Bayldon mentions that the stopes have been narrowed and that the breaking of the roof is cleaner. This has slightly raised the mining cost, but it has substantially increased the grade of the ore milled. In order to meet the cost of the fire, and to provide for further extensions, 105,488 priority shares of £1 each were issued in November last. These were subscribed by the parent company, the Siberian Proprietary.

### MELBOURNE, AUSTRALIA

A VICTORIAN SCANDAL.—MT. LYELL DIFFICULTIES.—QUEENSLAND'S DECLINING GOLD YIELD.—BROKEN HILL'S RECORD.

The mining sensation of the past two months in Victoria has been afforded by the affairs of a mine at Daylesford known as the North Nuggety Ajax. Daylesford is a field of many and erratic veins, the value of the ore being variable and the trend of the orebodies very unreliable. The North Nuggety Ajax, however, has won distinction by the market operations which accompanied the extremely sudden decrease in the gold content of its richest lode. In March last the market value of the shares was about \$21.50, and the official reports were of a roseate hue. Then a mysterious decline began, and a warfare commenced between two hostile parties. They were not mere market bulls and bears, anxious to boost the shares so as to be able to sell to advantage, or to bring down prices in order to buy cheaply, but genuine believers and disbelievers in the official assurances that all was looking

well. It was apparent that information from certain mines was diametrically opposed to that put forward by the management of the Ajax, and so many shares changed hands in the market. Obviously, some one was wrong as to the state of affairs at the mine, and ultimately the verdict of the Exchange was that the management was wrong, for the shares dropped to \$5. The crash came when it was announced that no dividend would be paid, as some liabilities of the company required settlement. The directors, if they were doing their duty, must have been well aware of the state of the finances, and had authorized the payment of a 75-cent dividend during each of the two preceding months, instead of reducing each of these amounts to 50 cents. The general opinion is that certain of the directors have deluded and deceived the shareholders and the public, in order that they might get out at good prices; but, though their manipulating of the market may be difficult to prove, there is a chance that they may be brought to task on the score of having paid dividends out of capital. The *Australian Mining Standard* has pointed out in a very outspoken article that the payment of dividends out of capital is not only a breach of trust for which directors are quickly and severely liable to make good with interest the amount misappropriated, but also it may render directors liable to criminal prosecution for conspiracy to defraud. It is not altogether unlikely that some such action may be taken in this case, for matters are rapidly coming to a head. The present position is peculiar. When the date was fixed for the half-yearly meeting of shareholders, a time was selected which little suited the Melbourne shareholders. It was hoped that the Melbourne men, who were naturally dissatisfied with the actions of the management, would be unable to put in an appearance. By motoring from Ballarat on Sunday, they, however, managed to be present on Monday morning, and as they held the balance of voting power, the game seemed to be in their hands. The management, however, had a card up its sleeve. Two of the nominations for the directorate were declared informal, the name of the company not having been correctly given. The main body of shareholders would not submit to this ruling, with the result that the meeting split, and two separate lots of directors were elected. The present position is that the management refuses to acknowledge the directors somewhat informally chosen by the majority of the shareholders, and that the latter are now applying for an injunction to force the recognition of these gentlemen, and to restrain those chosen by the rival party from acting in a directorate capacity. The whole affair constitutes the greatest scandal to which Victorian mining has been subjected for many a day.

The Mount Lyell Mining & Railway Co., Tasmania, has never recovered the position it occupied before the strike of its employees in the latter part of last year. The result of smelting operations for the past 12 weeks is a total output of only 1317 tons of copper. At this rate, the production of the company, instead of being in the neighborhood of 8000 tons of copper per year, will be only about 5700 tons. The causes are many, but are not complicated, and two of them stand out with particular clearness. First of all, the grade of the ore is declining, last month's return of 402 tons of copper from 23,000 tons of ore giving a return of only 1¾%. Secondly, there is a great shortage of labor for the mines, and in consequence the output is not up to the requirements of the smelters, so that one of the few which had resumed operations since the strike has had to close down. The falling off in the grade of the ore is being met by various improvements and economies in treatment; but the shortage of labor is a much more serious affair. Of the 720 men at present employed about the mines, no very great percentage can be classed as skilled miners, and the efforts of the company to employ men from outside have not so far been very successful.

The outlook in Queensland is not bright. An attempt is being made to boom a new property, the Mt. Oxide,

but there seems little reason for a boom. As for the old fields, they are almost all on the down grade. Two of the great goldfields of the past, Charters Towers and Gympie, are steadily deteriorating, the former's yield from all mines having declined last year to 133,833 fine ounces, and the latter's to 50,954 fine ounces, a drop of nearly 14,000 oz. in the one case, and over 8000 oz. in the other. The Government is seriously considering the advisability of granting substantial subsidies for the encouragement of deep sinking in these districts, so that the deep ground may be more thoroughly and systematically tested than it has been hitherto. As the state's output of gold alone up to the close of last year has amounted to nearly \$370,000,000, the Government can well afford to be generous. Last year its income from the mineral industry amounted in rents, royalties, and fees to some \$160,000, and its expenditure on the industry to not much over \$250,000, so that the net cost of the industry was not great.

The figures just issued for the second quarter of the year constitute a record for the great Broken Hill field of New South Wales. The production for the period amounted to 72,869 tons of silver-lead concentrate, of the value of \$3,500,000, 167,801 tons of zinc concentrate worth \$1,500,000, and 8169 tons of silver-lead crude valued at \$130,000. The net value of the mineral output in the half-year was \$10,000,000; this also constitutes a record for the field for any half-year period in its history. The field is, in fact, looking wonderfully healthy at the present time, the only cloud on the horizon being furnished by the suggestion coming from a section of the workers that they should repudiate their four and a half years' agreement with the mine-owners, though not one-fourth of the time has yet run out.

## TORONTO, CANADA

PRODUCTION OF PORCUPINE MILLS.—NEW PLANTS TO BE ORDERED.—ACTIVITY IN MINING IN COBALT DISTRICT.

The Hollinger recently shipped two 95-lb. gold bars valued at \$41,040, the product of a three days run of the refinery. The Vipond also made, about the end of July, its first shipment since the fire of last year. All the Porcupine mills are working steadily, the aggregate amount of ore treated per day being given at about 715 tons. The percentage of extraction obtained at the Dome is stated to be 96, while the Vipond and the McIntyre each obtained 75. The Hollinger milling grade is averaging over 1 oz. per ton, the Dome grade is about ½ oz. per ton, the former milling ore closely representing an average of the mine, apart from the higher-grade sections, and the Dome ore taken as it comes from the present workings. The milling capacity of the Dome is to be increased by coarser crushing. The main shaft is rapidly being put down to the 400-ft. level. The Vipond will enlarge its amalgamating plant by adding four plates for separating the gold, which will give the mill a complement of 10 plates. Its old boilers have been scrapped and new ones placed. The vein has now been tapped on three levels and widens considerably at depth. At the McEneaney a vein in a drift on the 300-ft. level shows native gold and has widened from 33 in. on the surface to 6 ft. at depth. The shaft is being put down to 400 ft. The McIntyre has ordered a cyaniding plant, comprising Chilean mills, rolls, and cyaniding tanks, and will increase the capacity of the present plant to 100 tons per day. It is understood that results of development at the Dome Extension have been somewhat disappointing, as the stringers showing in the cross-cut on the 230-ft. level are so small and broken that profitable ore is hardly to be expected. In other workings the gold content is distributed over a wide area and the grade is low. John P. Heffernan, managing director of the Crown Chartered, reports that assays taken in three 5-ft. sections of the vein at the 100-ft. level give an average of \$21 per ton. A promising orebody 15 ft. wide in places is being proved on the 200-ft. level. The Foley-O'Brien is to be unwatered for inspection to determine whether operations

will be resumed. The company has \$130,000 in the treasury. Labor difficulties have arisen between the management of five Porcupine mines, the Vipond, McIntyre, Jupiter, Plenaurem, and McEneany, and their employees over a new schedule of wages, which was to have gone into operation August 1. The men protested against any reduction, while the companies contended that the present wages paid were fixed when the camp was new and living expenses were higher than at present, and that the proposed schedule was the same as that of the Dome and the Hollinger. The men have appealed to the Department of Labor at Ottawa, which will appoint a board of investigation, and in the meantime the operation of the new schedule has been postponed until September 1. The Lucky Cross mine in Swastika district has made another good find at the 100-ft. level, consisting of a 7-ft. vein which carries free gold and is stated to assay high.

The past few weeks have witnessed a great resumption of activity in Cobalt mining, and the list of mines and prospects supposed to be dead which are taking on a new lease of life is steadily growing. The Foster, formerly a dividend-payer, has been leased to C. B. Flynn, of New York, and Thomas Flynn has been placed in charge. The Silver Bar, lying south and west of Cross Lake, on which little development has been done, has been taken over on a working option by the Preston East Dome of Porcupine, and active operations begun. The Cochrane Cobalt is being unwatered preparatory to a thorough inspection and sampling of the veins. The Nancy Helen has been purchased by the Buffalo and the workings of the latter mine are extended to the Nancy Helen shaft. The Cyril Lake Mining Co. has been organized to operate the Airgold, and the shaft, now down 90 ft., will be put down to 150 ft. Other mines which have been reopened, or are being unwatered for tests, are the John Black, Columbus, Last Chance, Twentieth Century, Waldman, Silver Lake, and King Edward. The Bailey is preparing to ship a carload of high-grade ore to raise funds for further development. Mining is now being done at the 400-ft. level, with the shaft down to 450 ft. in the conglomerate. The Ontario Government has thrown open to prospectors, commencing August 26, 4000 acres of land in the Gillies Limit, lying south of the portion already disposed of. The area has been examined by officials of the Department of Mines, but no discoveries were made, and most of the claims on that portion of the limit which were sold by the Government are lying idle. The Imperial Privy Council has confirmed the decision of the Canadian courts that natural gas is not a mineral. The matter is one of considerable interest to many landholders in western Ontario, who purchased their property from the Canada Land Co., the latter reserving all mines and minerals, and afterward selling the mineral rights to natural gas companies.

## BOSTON

AGREEMENT BETWEEN BUTTE & SUPERIOR AND CLARK INTERESTS.—RAID ON LAKE COPPER.—ELECTRIFICATION OF N. Y., N. H. & H. RAILROAD.

Butte apex disagreements have usually proved to be 'irrepressible conflicts.' Hence incipient trouble between W. A. Clark and Butte & Superior was viewed with alarm. It now appears that the two interests, realizing the cost of a legal struggle over extralateral rights, are determined to have the matter threshed out amicably, if possible, and thus avert a struggle in the courts. It is understood in Boston that a new exploratory and development campaign has been worked out carefully and has been agreed to by the parties at interest in order to keep the question from going into the courts. The orebodies in dispute lie in the western portion of the Butte & Superior property, and in no way affect the big zinc orebodies which are being worked now in the eastern part. As a matter of market policy, Butte & Superior could probably well afford to dispose

itself entirely of the mooted territory, rather than engage in one of the characteristic Montana legal controversies with W. A. Clark. Butte & Superior had considerably more than its original capitalization clipped from its market valuation because of the first hint that it would have a legal tangle over apex rights with Mr. Clark. D. C. Jackling ridicules the talk of dispute, and says that both sides have agreed to carry on development extensively and ascertain exactly where the orebodies in controversy begin and end. The Clark people have also gone on record as saying that there will be no occasion for resorting to the law. Either because the lawsuit rumor has run the regular nine-day Marathon or because traders now actually believe the two interests will not engage in a legal fight, Butte & Superior has recovered partly from its recent reaction.

An attempt to raid Lake Copper, which was started by a Stock Exchange house in Boston a few days ago, came quickly to an end. The house which took this initiative had sent one of its members to the Lake country to investigate conditions, and this representative conceived the idea, after going down in the Lake mine, that the stock was selling too high. He returned to Boston and started forthwith a short-selling campaign, giving out the information that the property had been exaggerated and over-boomed and that it was not likely to prove more than a mediocre proposition. Prior to this move Lake had been more than usually inactive, selling around 37 to 38. This new selling pressure clipped off nearly five points. As a result, a banking house which is sponsoring Lake quickly formed a league with two rival Stock Exchange houses, and with their combined weight they stopped the raid. The truth about Lake seems to be that it is selling within bounds and will continue to give a fairly good account of itself. The property will scarcely realize the expectations it aroused in 1910, when it sold up to \$94 per share. The famous Lake lode has proved to be a good deal of a freak and nobody has a definite idea of its trend. The property is producing about 300 tons per day, of an ore which is above the Lake average in content, and is more than meeting expenses. Lake has sold this year 10 points higher than its present price, and with strong interests behind it, looks like a difficult property to raid anywhere under \$45 or \$50 per share.

An interesting report has it that the coal mines of the Narragansett basin will be used largely as power stations for a considerable electrification system radiating from Boston and Providence, including the change-over to that basis of the Boston & Providence line of the N. Y., N. H. & H. railroad. The New Haven line is electrified from New York to New Haven and is working very satisfactorily at that end. It is proposed now to electrify the Boston end similarly. It has been learned that Henry M. Whitney has been negotiating with the railroad interests to supply power from the Portsmouth or old Rhode Island coal mines at Narragansett, Rhode Island. Another rumor is that English capitalists are negotiating in a similar enterprise. New England coal finds it hard to overcome native distrust. This coal has been extensively distributed throughout New England, and is said to have given satisfaction, producing great heat when under heavy drafts. But the coal is slaty and graphitic to such an extent that people are slow to believe in its merit. Hence the interests controlling the deposits seem to be turning to utilizing the coal right at the mines themselves and delivering electric power to the railroads and other customers. The project is one which is of great interest to the copper people, as it takes from 4000 to 6000 lb. of copper per mile for single track standard electrification equipment.

The Lewisohn interests seem to be taking more interest in the Lake country than any other section, ever since J. Parke Channing's trip to that district early in 1911 and his examination of the properties for the proposed Calumet & Hecla merger. The latest option taken by the Lewisohns is on the Kukana property, adjoining Elm river on the north and west. They have given orders to acquire 1200 acres in that vicinity.

## General Mining News

### ALASKA

CORDOVA

The telluride of gold, which was found in a claim near Teikhell, on the Valdez-Fairbanks road, turned out to be mispickel, an arsenical pyrite. Somewhat of a slump has followed this announcement. A rush has started to the Aniak district, where a rich placer deposit is said to have been opened to some extent. This place is difficult to reach, freight being taken by way of the mouth of the Kuskokwim, the plan being to carry it up the Aniak in small gasoline launches.

The Valdez *Daily Prospector* of July 27, in reviewing the mining situation, says: "Although the season has been unusually backward, yet the situation from a mining point of view is most encouraging. We do not refer to the number of 'deals' made, as much as we do the work of actual and miner-like development going on at the present writing. There are a dozen properties in widely scattered localities, within the field immediately tributary to Valdez, where development in progress is carried on with a view to ascertaining the extent and permanence of the orebodies.

. . . Our faith in their permanence is unbounded. . . . There is a limit to our financial capacity in developing the immense orebodies lying on all sides of us. . . . With the close of this season, we will be in a position to demonstrate that our orebodies carry depth. As far as work has progressed, without a single exception, properties on the glacier, on Mineral creek, on Shoup bay, Columbia basin, and Port Wells have shown that depth gives us wider and richer veins between well defined walls. . . . We hope by fall to be able to show investors a sufficiently developed country, to justify the expenditure of large sums of money in opening producing mines. . . . Within five years Valdez will be the centre of a great free-milling camp."

The Tacoma claim on Slate creek has been sold for \$36,000. This property has produced over \$300,000 in placer gold, and still contains a fair area of ground, which will be worked by the hydraulic plant brought to the claim during the spring by one of the late owners. The old tailing will be reworked. The ground yields from 50 to 94c. per yard.

FAIRBANKS

A large dredge weighing some 700 tons, is to be started on Flat creek, when brought over from Dikeman to Iditarod. A fleet of small vessels is engaged in carrying the dredge in sections to Flat city, but the river is low at present. From Iditarod the parts will be transported overland to Flat city. Miners are doing well on Otter creek this season, and Keystone drills are being used to further test the ground. A 5-stamp mill has been started at the Newsboy Extension. This mill was made at Fairbanks. The owners are driving on the 70-ft. level, which is out 50 ft. from the shaft. It is intended to resume sinking from 130-ft. depth.

NOME

(Special Correspondence.)—The New Era Mining Co. is erecting a 4-stamp Hendy mill in Snow gulch, about seven miles from Nome, to prospect a group of 11 claims. There is a series of small veins on and near a contact of schist and limestone, which averages \$10 to \$15 per ton. Little work has been done. The veins occur both in the schist and limestone, and their position does not seem to affect their gold content. The strike of the vein is almost east and west, with a dip of 65° to the south. This company has been financed by business men at Nome.

Nome, July 27.

From 93 tons of placer tin, mined by the Buck Creek Dredging Co. last season, the net result from Liverpool, England, was \$48,000. This quantity of tin ore was produced after 35 days' work.

Word from Seattle, Washington, states that the steamer *Victoria* reached that port on August 10, from Nome. She

had on board 283 passengers and \$543,000 in gold bullion. The heavy passenger list is on account of many miners, who have left the Seward Peninsula and Yukon valley, placer mining being restricted by scarcity of water, following the small snowfall of last winter.

### ARIZONA

COCHISE COUNTY

The Leonard Copper Co. is shipping 120 to 180 cars of ore per month to the Clifton smelter. It is somewhat low in copper content, but is a good fluxing ore. The Minneapolis company has 20 men at work, and is mining at 550 ft. Regular shipments are being sent to the Copper Queen smelter. It has been decided to build a 350-ton mill and cyanide plant at the Common-Wealth property at Pearce.

The production of copper from the Phelps-Dodge mines totaled 12,994,253 lb. in July, against 12,759,184 in June. The Copper Queen mine yielded 6,589,512 lb.; Montezuma, 3,092,016 lb.; and 1,118,635 lb. was recovered from custom ores.

GILA COUNTY

(Special Correspondence.)—The production of the Miami Copper Co. for July was a little over 3,000,000 lb. of fine copper, the highest monthly production to date. During the month there was mined 96,403 tons of ore, dry weight, and 4942 ft. of drifts and raises were driven. The third 8-ft. Hardinge pebble-mill has been added to the equipment of the fourth unit of the concentrator, giving a slight increase of capacity. It is believed that monthly production will be maintained close to 3,000,000 lb. of copper. A large proportion of the ore mined comes from square-set mining next to the capping, and from development, the rest from the shrinkage stopes and from the dump at No. 2 shaft. The new machine-shop at No. 4, or main shaft, is finished, and is being equipped. A building to contain the mine and engineering office is nearing completion. A contract has also been let for the steel work of a large new change-house, 57 by 90 ft., two stories high, and designed to accommodate 650 men. Development by diamond-drilling continues on the 570-ft. level, but considerable difficulty is experienced in obtaining a core. The northeastern territory is being prospected by two churn-drills. About 1000 men are employed, of whom 550 are underground.

The contract for railroad construction at the Inspiration Consolidated mines has been let to McArthur Brothers, and work should be started within the next two or three weeks. H. Kenyon Burch has established his office at the Inspiration camp, with a force of draughtsmen and assistant engineers. The chief draughtsman is George H. Booth, who held a similar position with Mr. Burch during the construction of the Miami concentrator. A temporary engineering office building, 30 by 120 ft., is being erected near the millsite. It will be occupied by Mr. Burch and his assistants when completed. The development of the Inspiration mine is proceeding at the rate of 4500 ft. per month. The two main working shafts are being sunk. The first haulage level is being opened at many points, the ore being hoisted through the Joe Bush shaft. Stations and ore-pockets are being cut at the first haulage level in the Scorpion and Colorado shafts, and an incline is being driven from the main tunnel to the surface. After this is finished, a hoist will be erected and the incline will be sunk to the haulage levels, and will be used exclusively for men and timbers. At the Live Oak mine, a pumping station is being cut at the 1160-ft. level in No. 2 shaft, and a steel head-frame is being erected at No. 1 shaft. After this work is finished, the sinking of the latter shaft will be resumed. The Sulphide tunnel is being widened to 7½ ft., and will be equipped with double track for electric haulage. Churn-drill hole No. 2, of the South Live Oak Development Co., has been stopped at a depth of 755 ft. in granite-porphry, without discovering chalcocite, though silicates and carbonates of copper were found. The drill is being moved to the hill in the schist area, at the northern end of the property adjoining the Needles group, and it is expected

that hole No. 3 will be started within a week. The schist is mineralized, and engineers who have examined the property think it offers a better chance of being ore-bearing than the granite-porphry area.

The Old Dominion produced 1106 short tons of blister copper in July. Engineers under H. Kenyon Burch are working on the plans for the concentrator. Proposals for steel work and machinery are in, but no contracts have yet been made. Construction will probably be started within two or three months. Concreting of the last section of the Kingdon shaft has been started, and should be finished in about two weeks. The section is 135 ft. deep, and the last three weeks have been spent in stripping this part of the shaft, that is, enlarging it from one to two compartments. The work is being done by Michaelson & Weideman, engineers and contractors. The Copper Hill shaft, at the Arizona Commercial, is being enlarged to three compartments above the fourth level; and there will probably be little other work done underground until the new equipment is erected, which should be within two or three months. The compressor at the Eureka shaft has been moved to the Old Dominion power-house, and a 5-in. pipeline has been laid from the power-house to the Copper Hill shaft. About 25 men are employed.

Globe, August 8.

## CALIFORNIA

### LOS ANGELES COUNTY

(Special Correspondence.)—Los Angeles members of the American Institute of Mining Engineers have been giving careful consideration to the report of the Committee of Five, appointed to study the condition of the Institute. Philip N. Moore, of St. Louis, a member of the committee on nominations, recently visited Los Angeles, and was invited by Seeley W. Mudd to meet a number of the local members of the Institute on July 15 at luncheon, at the California Club. Besides the host were present J. Morgan Clements, T. B. Comstock, C. Colecock Jones, F. A. Keith, F. J. H. Merrill, P. N. Moore, and W. F. Staunton. The general condition of the Institute was discussed at length, using as a text a preliminary copy of the report of the Committee of Five. On the following day a meeting of local members was held in the office of F. A. Keith, at which were present A. B. Carpenter, E. W. Carson, J. M. Clements, T. B. Comstock, W. M. Cummings, G. G. Damon, C. Colecock Jones, C. R. McCollum, F. J. H. Merrill, S. W. Mudd, P. N. Moore, S. Robinson, A. M. Strong, and W. L. Watts. T. B. Comstock presided. Mr. Moore addressed the meeting and requested suggestions regarding the management of the Institute and the nominations for officers at the approaching election. On motion, the chairman was empowered to appoint a committee of seven to act on the suggestions of Mr. Moore, and also to consider the matter of forming a local section of the Institute. In accordance with this motion, the following committee was appointed: F. A. Keith, chairman, A. B. Carpenter, W. M. Cummings, C. Colecock Jones, F. J. H. Merrill, S. W. Mudd, and W. F. Staunton. This committee will meet at an early date and take up actively the matters committed to its charge. This meeting was called hurriedly on account of Mr. Moore's brief sojourn in the city, and all the local members could not be notified in time.

Los Angeles, August 13.

### MODOC COUNTY

(Special Correspondence.)—The High Grade Merger Co. is being formed by C. L. Fulton and associates to work three claims recently acquired. These adjoin the Big Four and Josephine estate. The Sunshine claim is reported to have been leased to a party of Nevada mining men. It has been decided to sink 300 ft., and a contract has been let to George Cassell, former superintendent of the Home Run mine at Cripple Creek. The Lucky Dutchman No. 2 Leasing Co. has taken a lease on Block 5 of the Sunshine claim. Four men are at work and rich surface ore is being sacked. The same interests are working the Lucky Dutchman lease at the Yellow Jacket. It is

officially stated that work is to commence on the Sunset-Hammer claims, adjoining the Consolidated estate. James T. Wall, A. D. Armstrong, and other San Francisco people are chiefly interested. The new mine plant of the Modoc Mines Co. is nearly finished. It is said that the shaft will be deepened and extensive development undertaken. Good bodies of pay-ore are exposed. This company is composed of Chicago people, headed by William Wrigley, Jr. The Ft. Bidwell Con. Co. ordered a new boiler for its mill, and laid in over 300 cords of wood for the winter. The mill is treating ore from the Mountain View workings. A 2-ft. shoot of rich ore is reported as showing in the surface workings of the Gold Shore. The Big Four mill has been thoroughly overhauled, and is ready to commence crushing. Absence of adequate transportation facilities hampers shipment of ore from mine to mill. Prospecting is under way at a number of claims, and in several instances results are reported as encouraging. W. H. Storms, state mineralogist, visited the district this week. He appears favorably impressed with conditions, considering the present stage of development.

Ft. Bidwell, August 10.

### SHASTA COUNTY

(Special Correspondence.)—A new ore-shoot has been discovered in the southern portion of the Uncle Sam mine, six miles west of Kennett. Assays return about \$9 per ton. The find was made in virgin country and is considered important. The 10-stamp mill is working. The Uncle Sam has a record of \$1,500,000 from ore averaging \$8 per ton. It is being worked by the Standard Mining Co., of which H. D. Staley is general manager and S. W. Richards superintendent. The Afterthought Copper Co. has leased the recently acquired Terry railroad from Anderson to Bella Vista to the Terry Lumber Co. for the season. It is reported that the Afterthought interests paid \$200,000 for the line. Development is progressing in a small way at the mine, and experiments with the new treatment process continue. The new 5-stamp mill at the Gambrinus mine, near Stella, has commenced work. Four shoots of free-milling ore have been developed, ranging from six inches to four feet in width. Ore from all shoots averages about \$10 per ton. A good reserve of ore is reported to be opened. A 500-ft. adit has been driven at the Mad Mule mine, and work has started on an intermediate level. The completion of present work will give an approximate depth of 700 ft. below the old workings. The ore assays from \$3 upward. The Mad Mule recently passed under the control of F. M. Sponogle of San Francisco. W. G. Briggs is superintendent. The property is near Stella, in the Whiskeytown district. The North Star vein, in the Joe Davis group, is reported to be giving better results. A small crew is at work, and it is said that Eastern people have promised financial support.

Redding, August 13.

## COLORADO

### LAKE COUNTY (LEADVILLE)

The output of ore from Leadville mines during July was as follows: Western Mining Co., 10,000 tons; Iron Silver, 5000; Yak Tunnel, 11,000; Ibex, 6000; Colonel Sellers, 5000; Stars Consolidated, 5000; Castle View, 3000; Fryer Hill, 4000; South Evans, 3000; Sugar Loaf, 1500; minor companies, 4000 tons. The yield was slightly lower than that of June. About 50 tons of lead and iron ore is being hoisted from the Castle View mine. A good deal of zinc carbonate ore is also being shipped. The Sugar Loaf tunnel is in about 3600 ft., and good ore is being mined from the Dinero vein. Important work is under way in prospecting the Monarch vein, north into Prospect mountain; and will consist of extending the 500 and 600-ft. levels from the Silver Spoon north. The Monarch vein has already been followed for a distance of 3500 ft. from the north line of the Monarch, and is in ore for this distance. It is argued that the ore should continue, and the acquisition

of the Monitor and other properties will give ample country to prospect.

#### OURAY COUNTY

According to statistics collected by the United States Geological Survey, Ouray county produced the following in 1911: Ore treated, 133,252 tons; gold valued at \$1,952,958; silver, 512,800 oz.; copper, 564,273 lb.; and lead, 3,949,822 lb., with a total value of \$2,273,018. The county was fourth in Colorado in point of production. R. H. Elliott, of Berkeley, California, has been appointed mine superintendent of the Liberty Bell. W. H. Staver remains as general superintendent, and Mr. Elliott will assist him. The new mill at the Smuggler-Union is treating about 350 tons per day, 35 of which came from old dumps. The Wanakah company has made additions to its mill, resulting from the opening of a new lode in the mine some time ago. A pan to regrind the tailing from the Wilfley tables is being put in, and the pan product will pass over copper plates, and then be further concentrated on Deister and Wilfley tables. Besides the shipment of concentrate, several cars of high-grade ore have been sent to the Salida smelter.

#### SAN JUAN COUNTY

The new plant of the American Zinc Ore Separating Co. at Eureka, consists of an elevator, bin, Ruggles-Coles drier, trommels, and Huff electrostatic machines, the last to treat the zinc middling produced in the wet concentrating plant. About 90% of this product will pass a 150-mesh screen. The final zinc product is shipped to zinc smelters at Caney in Kansas, and the lead-iron-copper product to the Durango smelter.

During July, 132 cars of ore were sent out from the different mines, the principal producers being the Gold King with 35 cars; Silver Lake, 23; Sunnyside (lead ore), 18; Sunnyside (zinc ore), 17; Barstow, 13; and Iowa-Tiger, 11 cars.

#### TELLER COUNTY (CRIPPLE CREEK)

The Jerry Johnson mine, on Ironclad hill, shipped 32 cars of ore in July. This came from a new vein on the 650-ft. level. The Roxana company is suing the Doctor-Jack Pot company for \$1,000,000 for alleged trespass, and for ore wrongfully extracted. This will tie up valuable property for some time. The Doctor-Jack Pot company recently had judgment in its favor for a like amount, being the alleged profits made on ore wrongfully extracted by the Work company and its lessees. During the second quarter of this year the Doctor-Jack Pot shipped 837 tons of ore valued at \$21.40 per ton.

#### IDAHO

##### COEUR D'ALENE

The Bunker Hill & Sullivan company has paid another dividend, amounting to \$64,500, making the total to date of \$13,650,150. The high metal market is attracting numbers of mining men to the district. Properties in the Nine Mile and Mullan districts are being actively worked. A miner who was injured at 1000-ft. depth in the incline skipway of the Bunker Hill has brought suit against the company for \$30,000 damages. Work at the Giant Mining Co.'s claims on Sunset Peak consists of driving a cross-cut which will give a vertical depth of 450 ft. on the lode. The cross-cut is now in 670 ft., and a further 100 ft. of driving will be necessary. About 50 ft. per month is being driven. Samples taken from near the surface, in the 50-ft. drift being run from 150 ft. in the cross-cut, return gold, silver, copper, and silver and lead. The vein at this point is from 3 to 5 ft. wide. Annual assessment work is to be started on the 16 placer claims on Moose creek. The Tamarack & Custer Mining Co., incorporated under the laws of Nevada, has a capital stock amounting to \$2,000,000. It is said that a 300-ton concentrator will be erected at the Callahan property in the Sunset district. A great deal of ore has been opened in this mine.

A heavy flow of water was encountered in the tunnel of the Ajax mine, near Burke. Some time ago this tunnel was started a short distance from the Hercules No. 3 tunnel,

and after 150 ft., good ore was opened for about 300 ft. Later on, a tunnel was purchased in Moonlight ground, 2400 ft. lower down the mountain from the Ajax workings; and was continued for 2400 ft. The country rock is somewhat similar to the Hercules ground. During the year ended June 30, the Snowstorm mine produced 32,014 tons of ore, of which 29,964 tons was shipped, and 2050 tons milled. The total earnings were \$177,939; operating expenses, \$99,294; development and improvements, \$62,867; leaving the net profit at \$15,778. The cash balance is now \$48,645. The first unit of the concentrator is at work; and the second unit should be ready by September 15, which will make the mill's capacity 200 tons per day. It is hoped that the Coeur d'Alene district will support the Spokane Interstate Fair, in October, and send in exhibits relative to the mining industry.

#### MONTANA

##### CASCADE COUNTY

(Special Correspondence.)—At the B. & M. smelter of the Anaconda Copper Co. a new upright converter of the 'Great Falls' type has just been blown in. This converter is 20 ft. diam. inside the shell and 17 ft. high. The lining is of magnesite brick, 2½ ft. thick on the tuyere side, and 2 ft. thick on the opposite side. There are 62 tuyeres 1¾

GREAT FALLS CONVERTER.

inches in diameter, and the air consumption is 25,000 cu. ft. per minute. The total weight of the converter filled with metal is nearly 300 tons. The weight of the initial charge of matte is 65 tons and about 50 tons of copper will be produced from each pour. In the first run 135 tons of copper was produced from 24 hours actual blowing time, and 100 tons per 24 hours lapsed time. The converter was built in the shops of the B. & M. plant, with the exception of the castings weighing 13 tons each, which came from the Great Falls Iron Works.

Great Falls, August 7.

##### SILVERBOW COUNTY

(Special Correspondence.)—Shaft-sinking at the Pilot Butte has reached a depth of 1340 ft. The new hoist has arrived from Milwaukee, and is being erected. After this is finished the shaft will be sunk to 2000 ft. The Berlin claim of the North Butte company is expected to be cut at a depth of 1800 ft. Negotiations are pending between the Barnes-King and North Moccasin people whereby the former will operate the latter's property. These two mines adjoin. The Moccasin was equipped with good machinery, and before the shaft caved in showed profits on operations. Some large orebodies were opened, and the Barnes-King should do well. The Anaconda company has decided to increase the wages of its mechanics, on the lines of the increase given to miners and smeltermen. The mechanics, including all skilled laborers, will get an increase of 25c. per day as long as copper remains above 15c. per pound. The increase applies to the men employed at Butte, Great Falls, and Anaconda. The Tuolumne company is sinking its shaft from 1800 ft. some 400 ft. deeper. Second-class ore amounting to 250 tons, and 50 tons of first-class are being sent to the Washoe smelter. With copper at 17c. per pound,

a profit is made on this second-class ore. The Anaconda company has bought the Oro Fino mine, in the Georgetown district, for \$250,000. It joins the Southern Cross, which the company bought for \$500,000 some time ago. It would seem that the company is to develop the district fairly well, so owners of small properties are pushing work also. The Butte, Anaconda & Pacific railroad should be finished into this district by November. A good deal of work is under way at the Tramway mine, and the Berkeley is producing 14,000 tons per month. The Butte-Alex. Scott continues to ship about 250 tons of 6% copper ore to the East Butte smelter. A new hoist is being erected, after which the shaft will be deepened. In consequence of the assertion of W. A. Clark that the Butte & Superior company was encroaching on Elm Orlu ground, well-known engineers are studying the properties. The former's mill is working well.

Butte, August 12.

## NEVADA

### ESMERALDA COUNTY

From the 1300-ft. level of the Grizzly Bear mine, at Goldfield, regular shipments of ore are being sent to the smelters at Tooele. Until the 7 by 18-ft. shaft at the Goldfield Merger mines is down 2000 ft. it is not intended to open out. At the depth which will correspond with the 1400-ft. level of the Grizzly Bear mine of the Consolidated, a cross-cut will be driven from the Merger shaft to the west, to meet one to be started from the former for the purpose of ventilating both mines. The Goldfield-Florence shaft is down over 1185 ft. and at about 1200 ft. it is intended to open out. The Jumbo Extension has started to ship ore to the Bonnie Clare mill, 36 miles south of Goldfield.

### NYE COUNTY

High-grade ore is being stoped at four places in the Kendall-Douglas lease of the Manhattan Consolidated. A raise was put up after cutting the ore to a height of 35 ft., and the ore is from three to eight feet wide. There are 90 tons in the ore-bin. The Big Four company has opened a rich vein on the 500-ft. level. Ore up to 30 ft. wide has also been proved on this level. About 20 different placer claims are busy, and some of them yielding rich gravel.

During the week ended August 10 the mines at Tonopah produced 9957 tons of ore valued at \$248,925. The Belmont sent 1600 tons to the Millers plant and 2110 tons to the new mill. About 130,000 gal. of water per day is being pumped from level No. 13. A pump is being erected at the collar of the shaft to elevate the water to the water-tanks at the mill. Twelve feet of ore shows in the drift on level No. 13. The usual stoping was in progress on the 1166-ft. level. On the 1100-ft. level the intermediate west drift on the shaft vein has been stoped; but 5 ft. of good ore was exposed. The new mill is working satisfactorily, and should be up to full capacity next week. At the Tonopah M. Co.'s mill 93 stamps ran full time for the week ended August 3, and crushed 3225 tons of ore worth \$18, with 90% extraction. Thirty-six bars of bullion worth \$45,000 and 20 tons of concentrate worth \$9000 were shipped from the mill. In the Silver Top mine a new stope has been started on the foot-wall vein at the 240-ft. level, where it is three to four feet wide. The new stope on the 200-ft. level of the Mizpah mine is also this width. The raise from the 700-ft. level in the Desert Queen is being continued in three to four feet of low-grade ore. In the Red Plume stoping and driving are in progress east on the south vein on three feet of good ore. The shaft of the Tonopah Merger is down 40 ft. below the 980-ft. level in hard formation. During July the West End Consolidated treated 3184 tons of ore producing 41 bars of bullion and 29 tons of concentrate. The eastern workings on the 500-ft. level continue to show about 18 ft. of ore assaying from \$25 to \$36 per ton. From 14 to 22 ft. of ore is being mined west of the shaft stope 555. This stope is 120 ft. long and is being worked up to the 400-ft. level. The Tonopah Extension

produced \$63,200 from 4503 tons of ore. The stopes generally are yielding good ore. During July the new shaft was sunk a further 115 ft., while a total of 787 ft. of development was done in the mine. In the Montana-Tonopah 938 ft. of work was carried out in July, and the output was 4485 tons of ore, from which 31.7 tons of concentrate was produced. It is expected that a better extraction will be made when the new Trent agitator is at work.

### STOREY COUNTY

During the week ended August 10 the Mexican mine yielded 195 tons of ore worth \$56.08, and 23 tons worth \$106.46 from the 2500-ft. level; 396 tons containing \$7506 from the 2400-ft. level; and 6 tons valued at \$41.46 per ton from the 2300-ft. level. The mill crushed 506 tons averaging \$22.60 per ton, with 93% extraction. The Ophir shipped 272 tons to the Kinkead mill. At the cyanide plant the tube-mill foundations are finished, also those for the Dorr thickeners, three agitators, and stock tank. Framing of the building is nearly finished. From the stope in the southwest drift at the Consolidated Virginia, 27 tons of ore was mined, assaying \$19.22 per ton. On the 2300-ft. level the west cross-cut is out 115 ft. in quartz and porphyry of low value. At the Union Consolidated the blower station near the Union & Sierra Nevada winze has been cut out. In the Yellow Jacket shaft water is now 38 ft. 11 in. below the 1400-ft. station. The pumps in the C. & C. shaft worked from 150 to 160½ hr. during the week, and the water was down 291 ft. below the 2200-ft. station. Timbering has been done below the 2300-ft. level. The Starret pump in the Ward shaft was under repair.

### WHITE PINE COUNTY

A man employed in the converter building of the Step-toe plant was electrocuted last week while at work on one of the overhead traveling cranes. The cause of the accident is not known.

## NEW MEXICO

### SOCORRO COUNTY

(Special Correspondence.)—The Socorro company has erected special ore-bins, and receives custom ore regularly. The 700 and 800-ft. levels of the mine were flooded, on account of a large flow of water being cut in the 500-ft. level on the Queen vein; and a concrete bulkhead is being built to stop the flow. The Ernestine battery of 20 stamps is being reconstructed. During the week ended August 9, 590 tons was treated, and the total output for the month amounted to 27,460 oz. of bullion and 14 tons of concentrate. An automatic sampler has been ordered, to deal with custom ore at the Deadwood mill. The 50-hp. gasoline engine for the mill is working. During July the output was 7050 oz. of bullion. The Pacific & Johnson produced 115 tons of high-grade ore, which goes to the Socorro mill for treatment. Both the Deep Down and Iron Group are sending their ore to the Deadwood mill.

Mogollon, August 9.

## UTAH

### JUAB COUNTY

Additional pumping equipment is to be used to unwater the 2200-ft. level of the Centennial-Eureka mine. The present electric pump has been lifting 1100 gal. per minute from this level. The Grand Central company has cut ore at a depth of 2300 ft., but assays are rather low so far. In the tunnel of the Lehi-Tintic, which is in 1450 ft., a number of promising veins have been found, while a cross-cut is being driven to prospect for the Empire vein. After diamond-drilling to 500 ft., the Dragon Consolidated stopped work, as compressed air for the machine had to be brought a long distance. Steam will probably be used later on. The May Day mine is to ship zinc ore to the smelters in Kansas. The mine is said to contain at least 10,000 tons of high-grade ore.

The Chief Consolidated is at present shipping four carloads of ore per day, and is arranging to have a branch

built from the Rio Grande railroad, so that ore can be loaded direct into cars.

#### SUMMIT COUNTY

During the week ended August 10, the mines in the Park City district shipped 1250 tons of ore.

#### SALT LAKE COUNTY

The mining men of Utah are thoroughly aroused to the necessity of completing some organization for the promotion of the welfare of the mining industry, and a meeting is to be held for the purpose of getting the members of the mining committee closer together, and determining whether Utah metal producers should form an independent organization, or revive the state chapter of the American Mining Congress.

### WYOMING

#### ALBANY COUNTY

The Commercial company has started to cross-cut for the old Centennial lode, 458 ft. in the main adit. It is expected that the vein found in the cross-cut will be reached within 40 ft., and then be followed toward the main shoot. The small vein assays up to \$56 per ton in gold.

### AUSTRALIA

#### CHARTERS TOWERS (QUEENSLAND)

During May nine mills crushed 15,340 tons of ore for bullion valued at \$93,000; cyanide works treated 11,400 tons for \$36,500; smelters treated 212 tons for \$30,900 in gold, \$830 in silver, \$1130 in lead, and slag, \$1700; alluvial gold was won worth \$280; 106 tons copper ore yielded \$1850; and 32 tons black tin were valued at \$19,800, a total from all sources of \$193,460. Mining in this centre is now down nearly 3000 ft. vertical depth. Mills Day Dawn United at 2540 ft., is prospecting the deeper ground on the Day Dawn reef; and at the same depth the Brilliant Deeps is stopping pay-ore on the Brilliant reef; the Brilliant Extended development is now close on 3000-ft. depth. The Brilliant Extended crushed 3620 tons for \$18,000; Mills Day Dawn, 1566 tons for \$10,000; and Golden Horn, 5632 tons for \$9500. The latter is an interesting low-grade mine several miles from Charters Towers; the ore is quarried, crushed by 20 stamps, and the sand leached in vats, the residue being washed down a creek. The whole plant is driven by a suction gas-engine.

### CANADA

#### ONTARIO

A new factory for the manufacture of dinitrolite, a new safety explosive, has been started near Clear lake, for the Dominion Explosives Co. The plant will make from 10 to 15 tons of explosives per week for a start. Two men were sentenced to two years imprisonment for stealing about \$2000 of silver from the Nipissing mine. During July the Cobalt Lake mine yielded 100,000 oz. of silver, from high-grade ore shipped to the smelter, and part from ore milled at the mine. Additions to the concentrating plant are being made. It is probable that the Silver Islet Mining Co. will reopen the mine bearing that name. About \$3,500,000 was extracted from the mine many years ago, but water broke in and stopped work. The new shaft at the Ophir is down 145 ft. on a lode which is 4 ft. wide.

The shipments for the week ended August 3 were as follows: La Rose, 101.12 tons of ore; Nipissing, 64.93; Townsite, 43.63; Buffalo, 28.98; McKinley, 41.37; Cobalt Lake, 34.12; Hudson Bay, 31.79; Kerr Lake, 20; and Timiskaming, 30.99 tons. Silver bullion was shipped by the following mines: Nipissing, 112,142 oz.; Kerr Lake, 7339; La Rose, 24,180; Cobalt Townsite, 2984; Drummond, 1477; and Casey-Cobalt, 940 ounces.

#### QUEBEC

The annual report of the mines department of Quebec states that in 1911 the various mines produced minerals valued at \$8,769,786, an increase of \$1,356,505 over the preceding year.

#### YUKON

About 1200 bbl. of fuel oil arrived for the Yukon Gold

Co. on July 26, and is to be used as an experiment in generating steam for the company's thawing plants on the creeks.

### JAPAN

On July 17, fifty men were injured and one killed in the Okuma coal mine, in the Fukuoka district, owing to the careless use of a safety-lamp. For the first six months of the current year, Japan has exported coal valued at 10,245,355 yen, and copper at 10,419,009 yen. Imports included phosphates valued at 4,444,922 yen; pig iron, 4,545,634 yen; wire, bar, and plate 18,334,000 yen; rails, 2,473,565 yen; tube and pipe, 2,517,760 yen; kerosene, 6,204,655 yen; and machinery, 14,555,613 yen. The exports of gold and silver coin and bullion totaled 13,001,600 yen; and the imports, 8,923,669 yen.

### MEXICO

The *Boletin Fiscal* for the year 1910-11 has been issued by the Minister de Hacienda, and contains official records of the mining industry. The total value of mineral products exported for the year amounted to \$180,005,936, against \$156,520,075 for the preceding year. The past fiscal year has been the greatest, in point of production, in the history of the industry. Gold was exported to the value of \$62,090,505, a gain of \$19,454,103; while the silver totaled \$80,867,861, an increase of \$4,518,740. The base metal exports were as follows: Copper, \$26,300,228; lead, \$6,539,908; zinc, \$900,706; antimony, \$2,046,689; and quicksilver, \$438,369. There were 30,837 existing titles at the close of the fiscal year, embracing 442,541 pertenencias, a decrease of 318 titles. Sonora ranks first, with 5094 properties; Chihuahua, 5046; and Durango with 4028. The exports of all minerals to the United States amounted to \$137,853,411, which is 77% of the entire production.

#### CHIHUAHUA

A new 100-ton mill is to be erected at the north of the adit being driven at the Cababacilla mine, at Cababacilla, in the main range of the Sierra Madre. This mine is situated at a height of 4200 ft. and is 75 miles southeast of El Fuerte, Sinaloa, the nearest station on the Kansas City, Mexico & Orient railroad. The gold ore at Cababacilla occurs on the contact between an andesite and rhyolite, and is red and white in appearance, the gold being associated with iron oxide. The ore occurs in lenses, from 5 to 50 ft. wide and 10 to 110 ft. long, is free-milling, and is worth \$30 per ton in gold, with practically no silver. The main incline shaft is down 800 ft., and 10 levels have been opened 1300 ft. along the lode. Over 12,000 ft. of development has been done in the mine. The adit first mentioned will cut the lodes at a vertical depth of 1000 feet.

(Special Correspondence.)—The situation in the revolution is unchanged. Dolores is still cut off from railroad communication, but the officials of the Dolores Mines Co. have gone in from El Paso. The rebels are expected to move into northern Sonora by way of the Mexican North-western railroad.

El Paso, August 10.

### RUSSIA

(Special Correspondence.)—The platinum market at Ekaterinburg, in the Urals, shows little change, prices being somewhat under the quotations of a few months ago. There is a movement now to form companies to prospect the platinum placers of this district. Three companies have been formed: the Aktai Platinum Mines Co., with a capital of \$750,000, partly subscribed by Belgians; the Sosva-Ural Gold & Platinum Co., with \$200,000; and the Vagran Gold & Platinum Co., with \$750,000 capital. Their object is to get hold of the remaining platinum deposits of the Urals, which will be worked out before long. The present high price of the metal probably also has something to do with the formation of new companies. There is little to report from the goldfields of the district, and production remains much as usual. Many placer miners prefer to work on platinum, as it pays much better than gold.

St. Petersburg, July 23.

## Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

C. S. THOMAS is in California.  
E. F. BURCHARD is to go to Alaska.  
J. G. KIRCHEN is in San Francisco.  
RALPH ARNOLD is at Washington, D. C.  
F. G. COTTRELL has left Butte for the East.  
T. T. READ has gone to Great Falls, Montana.  
CLAUDE E. JAMISON is examining the Jumper mine.  
H. W. TURNER is in the Urals on examination work.  
GARNETT A. JOSLIN has gone to Caracas, Venezuela.  
SUMNER S. SMITH has left Nome for Katalla, Alaska.  
E. P. MATTHEWSON will be in San Francisco next week.  
CHETWYND INGLIS has arrived from Cobar, New South Wales.

E. D. McDERMOTT is in the Caucasus examining copper mines.

RENE DE LABEL is exploiting placers in the Trans-Baikal, Siberia.

JOHN W. FINCH is conducting exploration in northern Ontario.

C. A. ENGLEBROCK is examining dredging ground near Vladivostok.

CHARLES JANIN has returned from Nome and is at Seattle, Washington.

F. L. COLE is in Shanghai on business. He will soon go to Vladivostok.

A. C. PERKINS is in the Straits Settlements installing dredging machinery.

HARRY WOOD is assisting T. C. JAGGAR in the study of Hawaiian volcanoes.

L. M. DRURY, who was in San Francisco last month, is back at Fairbanks, Alaska.

H. W. HARDINGE is back in New York from his trip to London, Sweden, and Norway.

AUGUST HOFFMANN has resigned and will soon leave the Syssert Estate for Stockholm.

PERCY E. BARBOUR is in Boston for several weeks for business and pleasure combined.

G. E. GRUNSKY, JR., is now superintendent at the Standard Consolidated at Bodie, California.

STANLEY C. SEARS is now general manager for the Utah Apex Mining Co., Bingham Canyon, Utah.

S. B. CHRISTY, A. C. LAWSON, and A. S. EAKLE have returned to Berkeley for the winter's work.

LOYD C. WHITE passed through San Francisco this week on his way from Lucky Boy, Nevada, to Stewart, British Columbia.

R. E. SMITH, H. G. HAAN, N. C. STINES, and WILLIAM KNOX are examining placer ground under R. B. HOFFMANN near Nikolaievsk.

R. E. GARRETT, of the University of Oklahoma and the Oklahoma Geological Survey, has been appointed assistant in mineralogy at Northwestern University.

The engagement is announced of EUGENE P. KENNEDY, assistant superintendent of the Alaska Treadwell Mining Co., to Miss THERESA KEENEY, of San Francisco.

D. M. FOLSOM, who has been assisting in the editorial work of the *Mining and Scientific Press* for the summer, has returned to his regular duties at Stanford University.

J. P. HUTCHINS and J. F. ERDLETS have just finished examining mines in the Nerchinsk district for the Russian Government, and have gone to Blagovestchensk on the Amur river.

MORTON WEBBER has terminated his association with C. L. Constant & Co., and has opened an office at 2 Rector street, New York City, where he will continue to specialize in mine valuation and development.

OTTO WARTENWEILER, who has been in charge of the mechanical design and construction of the new mill of the Tonopah Belmont Development Co., has gone to Pearce, Arizona, where he will act in a similar capacity for the Common Wealth M. & M. Company.

## Market Reports

### LOCAL METAL PRICES

San Francisco August 15.

Electrolytic Copper.....	18-18½c	Tin.....	60-51½c
Pig Lead.....	4.75-5.70c	Spelter.....	8-8½c
Zinc dust, 1400 lb. casks, per 100 lb., small lots \$9.50-9.75; large \$7.50-8.50			

### METAL PRICES

(By wire from New York.)

NEW YORK, August 15.—Copper prices are firm, despite the increased supplies and large production reported by the Copper Producers' Association last week. This is attributed to increased demand for domestic consumption and is considered very favorable. Lead market firm and metal is in good demand. Spelter is quiet and somewhat weaker.

Average daily prices for the past week, in cents per pound, based on wholesale transactions, standard brands, are given below.

Date.	Electrolytic Copper.	Lead.	Spelter.	Silver, per oz.
Aug. 8.....	17.45	4.50	6.75	60½
" 9.....	17.40	4.50	6.75	60½

## Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

**LEAD** acetate used in cyanide plants does not always result in a decreased consumption of cyanide, or an increased extraction.

**GAS** for engine power is now derived from many sources. It is stated that an engine in New South Wales makes power from the gas issuing from a septic tank. This ought to be economical.

**EXHAUST** from three gas-engines at a new mill in Western Australia is conducted into the firebox of a locomotive type boiler, and about 10 hp. is developed; enough to drive a dynamo for lighting.

**ANIMIKITE** is a doubtful mineral species, containing silver antimonide, which is allied or perhaps identical with dyscrasite. It occurs in the Silver Islet mine, Ontario, associated with Hunttilite, a silver arsenide.

**SEPARATE** houses are considered advisable by many metallurgists for copper plates in the interest of safety, and close supervision; likewise all tube-mills, vanners, and other departments are occasionally placed in separate buildings.

**WHEN** excavations are being cut, for foundations, in gravel or loose rock, a cheap method is to sluice the waste away, as has been done fairly often, notably at Seattle, and for battery foundations at mines in New Zealand.

**CHROMITE** has been produced outside of the United States during recent years mainly in New Caledonia, Rhodesia, Asia Minor, Russia, Greece, Canada, India, and Japan. Rhodesia and New Caledonia at present are among the most important producing countries.

**ANTIMONY** is used principally in antimonial lead as type metal and as babbitt and other bearing metals, in coffin trimmings, linings for acid tanks, toys, clock cases, and other articles for which a fairly hard metal to be gilded or otherwise finished is desired.

**CLASSIFICATION** of mill pulp has reached a fine point in some places, even to the extent of becoming very complex and being overdone. During the past year or more, the Ivanhoe company at Kalgoorlie cut out a number of small classifiers and recovery was not lowered.

**TUBE-MILLS** in the plant of the Waihi-Paeroa Extraction Co., of New Zealand, on being started after 24 hours' shut-down, were found to run out of balance, resulting in breakage of driving gear. It was found that this was due to the pulp and pebbles setting hard in the mills.

**FILTER** leaves made of corrugated iron show the same tonnage efficiency and good wash as do those made of cocoanut matting in a leaf of a vacuum plant. The matting is liable to become choked with slime if the filter-cloth leaks, and also choked with lime compounds. This is Waihi experience.

**ROPES** used for driving shafting always make trouble in that one rope is tighter than another and does more work. Some millmen prefer one long endless rope, usually running around a grooved tension pulley. If the splice pulls out of the ropes there is a long shut-down, whereas if one of a number of driving ropes pull out, the others will take up the extra load.

**OWING** to the shut-down of the plants at Waihi on account of the strike, most of the Brown agitators were left in all stages of being filled, agitated, and emptied. During the first few weeks it was the practice to give the slime a blow with air, no trouble being found in re-starting. It was decided later to leave the tanks alone, as the slime seems to settle to a certain consistence, and remain so, while further agitation may destroy this.

**MAGNESITE** is supplied on the Pacific Coast in quantities greater than the demand. Very little dead burnt magnesite is made here, owing to the cost of fuel and labor. Most of the magnesite of this quality comes from Greece, Austria, or Norway, and commands a price of about \$23 to \$25 per ton, according to quality. Prices are quoted monthly in the *Mining and Scientific Press*. Precipitated magnesium carbonate is a different material.

**MOLYBDENITE** is the chief source of molybdenum, which is used in steel-making as a hardener, and in chemical industries in the form of ammonium molybdate and other salts. Two methods of production are in general use; the aluminothermic, and the electrical. The former yields a product free from carbon, but containing small quantities of silicon, and from 1 to 2% of iron. The electrical process consists of heating the ore in a carbon tube, employing a current of 350 amperes at 60 volts. A portion of the sulphur is thus expelled as SO<sub>2</sub>. By increasing the current to 900 amperes the mass is fused and the sulphur completely expelled. The metal thus produced contains about 7% carbon, which may be removed by heating the metal with molybdic oxide. Buyers require concentrate to contain 90 to 95% molybdenite, and the price fluctuates between \$400 and \$500 per ton. The crude ore is concentrated, like any other mineral, by ore-dressing processes.

**WATER** from mines and other sources has a corrosive effect on iron or brass pump parts, and also on iron pipe. The use of wood pipe has helped greatly to reduce this trouble. Very bad water was met with in a mine at Carterville, near Joplin, and a pump made of wood and lead has been specially ordered. It will be a 4-in. two-stage centrifugal pump, the spindle of which is of brass, and similar to two pumps working at another property in the district. The delivery pipe will be coated with an acid-proof paint. At the Associated mine, Kalgoorlie, wood pipe of 3, 4, 5, and 6-in. size replaced iron pipe at many parts of the surface plant, with great success, one line being used for returning furnace water at 140° F. to a cooling tank. It is also used on other mines in Western Australia. The Australian Wood Pipe Co., of Sydney, has recently secured a contract to make 14 miles of 18-in. wood pipe for the new water system for Broken Hill. This contract is worth \$200,000.

**POTASSIUM PERMANGANATE** has been used in South Africa as a preliminary wash, especially in the treatment of pyrite. It should, however, be removed by a water-wash prior to cyanide treatment, as any excess remaining in the solution reacts with and destroys cyanide. In some cases a mixture of permanganate and sulphuric acid has been used for the preliminary oxidation and removal of cyanides. Certain oxidizers are ineffective in cyanide work, and in practice, when air is not used, permanganate, sodium dioxide, and bromine have been used to assist in solution of gold. During milling operations ferrous sulphides are formed, which attack solutions. The remedy is to supply oxygen artificially in the form of air, or an oxidizing agent. From two to eight ounces of permanganate per ton of slime have been used. The reactions of permanganate with ordinary mill solutions are somewhat complicated, many compounds being formed in alkaline solutions, and it does not appear to be known with any certainty how permanganate acts in aiding solution of gold. For the estimation of ferrocyanides and the use of permanganate, see Clennell's 'Chemistry of Cyanide Solutions.'

## Company Reports

### NEVADA-DOUGLAS

The annual report of the Nevada-Douglas Copper Co. for the year ended March 31, 1912, states that the mines in the Mason mining district of Nevada produced 23,937 tons of copper ore and 7299 tons of gypsum, with a return of \$152,429, and after deducting \$105,560 for all expenses there remained a profit of \$46,869. Final settlements on ore shipments are expected to give \$33,101 profit. Ore from the Ludwig mine averaged 5.62% copper, and the reserves are estimated at 289,000 tons. In this mine 2261 ft. of development work was done. The most important results were on the sixth and seventh levels. A cross-cut has been driven 120 ft. near the south face of the former level, and the hanging wall of the lode had not been reached. The cross-cut is in carbonate ores and leached material. This enlargement is in the vicinity of a porphyry dike. The Douglas Hill mine has reserves of ore totaling 350,000 tons. Its average during the period was 5.24% copper. Four hundred and sixty-three feet of development was done, showing that strata of barren limestone alternate with lodes throughout the deposit. The Copper Basin mine averaged 5.06% copper, and 106 ft. of sinking in the main shaft passed through alternating beds of ore and limestone. Reserves are given as 50,000 tons. A Gould pump was put in to lift the water from 780-ft. depth in the incline shaft. So far, returns from gypsum shipments have not been very profitable. The quarry where this mineral is mined is 50 ft. wide, with a vertical face 35 ft. high. There is a small overburden. The rock is elevated to a crusher, broken to 3-in. size, and shipped away. The gypsum carries 24% moisture and averages 96%. The erection of a smelter for the copper ores is to be considered at an early date. The company holds a half interest in the Nevada Copper Belt Railroad Co., whose earnings for the first three months of 1912 were \$44,656, and expenses \$39,811.

### ALASKA TREADWELL G. M. COMPANY

The financial year of this company has been changed to conform with the calendar year, hence the twenty-first report covers the past 19 months to December 31. During this period 15,533 ft. of development was done on eight levels, making a total of 122,563 ft. for the past 18 years. The Treadwell company also did 931 ft. of work in the 700-Ft. Claim mine. Little development was done on the 440, 750, 900, and 1050-ft. levels, and nothing was done in the open pits. On the 1250-ft. level the No. 4 east drift was connected by a cross-cut 65 ft. long, with No. 3 east drift. This was to improve the ventilation through the raise from 1450 ft. Seven samples from the above 65 ft. averaged \$2.93 per ton. Work was done from No. 4 south cross-cut, which was necessary for stoping 50,000 tons of ore left on the foot-wall between the 1250 and 1050-ft. levels. Most of the development work on the 1450-ft. level consisted of intermediates, manway drifts, and raises for chutes and stopes. The stopes on the level are about half completed, and contain 769,130 tons of broken ore ready for the mills. The main cross-cut on the 1600-ft. level was continued 603 ft. through waste, after which the lode was cut. The cross-cut was then turned west and continued 421 ft. through ore to the hanging wall. Seventy samples, taken across this 421 ft., averaged \$4.14 per ton. No. 1 east drift was driven 236 ft., the first 88 ft. being ore, the balance waste. Thirteen samples assayed \$6.96 per ton. Work on other cross-cuts and drifts went through ore of a fairly high average. At the 1750-ft. level the main cross-cut was driven 883 ft. through waste, and 36 ft. of ore, which assayed \$3.13 per ton. The No. 3 east drift in the main cross-cut was driven 19 ft., which gave \$2.22 per ton; while No. 7 west drift, opposite the former, was advanced 14 ft., assaying \$2.27. During the 19 months under review, 1,349,264 tons of ore was extracted from the 750, 1050, 1250, 1450-ft. level

stopes, and development on 750, 900, 1050, 1250, 1450, 1600, and 1750-ft. levels. The ore reserves totaled 7,613,087 tons, made up of 6,344,749 tons in place, and 1,268,338 tons broken in stopes. The average of 6193 samples from the mine was \$3.32 per ton. The 240-stamp mill crushed 633,976 tons, with a duty of 4.64 tons per stamp, and the 300-stamp mill 715,288 tons, equal to 5.44 tons each. Both mills produced 24,952 tons of concentrate, of which 17,751 tons was treated at the mine by cyanide, full details of which appeared in the *Mining and Scientific Press* of June 29. The total yield from 1,349,264 tons milled and concentrate treated was \$3,259,446. Dividends paid amounted to \$800,000. The yield per ton milled was \$2.41, and costs totaled \$1.43 per ton. The report, which covers 74 pages, and several mine plans, is a creditable production and leaves nothing to be desired.

### NIPISSING MINES COMPANY

The seventh annual report of this company, operating mines at Cobalt, Ontario, shows that it had a year of high production of silver at a low cost per ounce; a large profit was made and dividends paid; the cash surplus was much increased; the high-grade ore is now being properly treated at the mine, while a plant for the treatment of the low-grade ore is being constructed, also at the mine. During the year, 29,146 tons of ore was shipped, assaying from 273 to 2393 oz. silver per ton, yielding a total of 4,678,074 oz., worth \$2,506,608. The average price received per ounce was 53.58c. For 2356 lb. of cobalt sold, \$589 was realized. Freight, treatment, and smelter deductions totaled \$125,484, which left a net value received of \$2,381,712. The total cost of producing silver, based on an output of 5,197,042 oz., which was contained in the shipments and ore on hand, amounted to 13.95c. per ounce. There was on hand at the end of 1910 ore amounting to 185 tons, and at the end of 1911, 268 tons; so with the shipments during the latter year, the mine production totaled 2992.39 tons, containing 5,197,042 oz. silver, with a gross value of \$2,820,257. The total profit on production was \$2,095,241. The shipments from 1904 to the end of 1911 amounted to 24,475 tons, valued at \$12,939,395. Dividends for the year were \$1,838,430, making \$7,850,930 in all. Twelve veins contributed to the past year's output, No. 73, 80, and 100 yielding 3,142,198 oz. A new hydraulic equipment, for surface prospecting, was fitted up. A force of 25 men completed 13.7 miles of trenches 2.7 ft. deep. In the diabase, east of the lake, No. 149 vein was found to contain high-grade ore. Of the 846 acres held, 576 are partly prospected, and 270 unprospected. A total of 8781 ft. of development, and 13,841 cu. yd. of stoping was done. The year's work on vein 73 has been most favorable, and on the 247-ft. level it has been opened for 200 ft., the average width being 4 inches. A fault disturbed veins 80 and 100, between the 70 and 189-ft. levels, but they have been picked up again. Vein 64 is the strongest on the property, and has been developed on five levels to 344 ft. deep and 900 ft. long. Vein 122 did not realize expectations; but 63, 108, and 148 produced heavily, although the high-grade ore in them is nearly exhausted. The reserves consist of 7 veins containing 3454 tons of ore with 6,126,838 oz., and 80,036 tons on the dump, with 1,756,954 oz. silver. Treatment of the high-grade ore was started in February 1911. The process, described in detail by T. A. Rickard in the June 1912 issue of *The Mining Magazine*, consists essentially of amalgamation in cyanide solution in a tube-mill, where 97% of the silver in the ore is recovered as amalgam. The tube-mill pulp is further treated in a cyanide plant. This new mill dealt with 922 tons of ore, from which 2,522,888 oz. of silver was recovered. For the treatment of the low-grade ore, assaying about 22 oz. per ton, a mill of 40 stamps, with 200 tons daily capacity, is being erected. The stamps will weigh 1500 lb. each, following which there will be four tube-mills, amalgamation if necessary, agitation with cyanide, a Butters filter, and Merrill zinc-dust precipitation.

## Decisions Relating to Mining

Specially reported for the MINING AND SCIENTIFIC PRESS.

### GROUP OF MILLSITES—POSTING OF NOTICE

Where two or more contiguous millsites are embraced in a single application for patent, the posting of one copy of the notice and plat within the limits of the group is sufficient, without the necessity of posting a separate copy upon each claim.

Phoenix Gold Mining Co., 40 Land Decisions, 313. December 1, 1911.

### OIL LEASE—FORFEITURE FOR BREACH

Under an oil and gas lease providing that it should be void unless a well is completed before a specified date, or unless, after that date the lessee pays a specified rental, a failure to either complete the well or pay the rent is a breach of the condition working a forfeiture of the lease, and not a breach of covenant entitling the lessor to recover the rent.

Butcher v. Greene (Indiana), 98 Northeastern, 876. June 18, 1912.

### FELLOW-SERVANT RULE ABOLISHED IN MINES

A state statute abolishing the fellow-servant rule in mine accidents, but limited in its application to employees in mines producing mineral, and exempting from the liabilities imposed prospectors and others whose mines have not reached the point of production, has been held constitutional and not class legislation. The unusual hazards incident to the duties of miners who work beneath the surface furnishes adequate support for the distinction made in the act between classes of miners engaged in duties distinctly different in character and with respect to the dangers attendant upon them.

Hawkins v. Smith, (Missouri) 147 Southwestern, 1042. May 20, 1912.

### COAL-LAND ENTRY—REPAYMENT OF PURCHASE PRICE

Where a person makes a coal-land entry, avowedly for his sole use and benefit, but actually at the instance of a corporation, with its money and for its benefit, the entry cannot for this reason be deemed to have been fraudulently procured in contravention of the Federal statute which forbids the acquisition of such lands in excess of the quantities prescribed, where there is nothing to show any effort through this or like entries to evade the restrictions in respect of quantity. Where such person assigns his rights by quit-claim deed to the corporation for whose benefit the entry was made, and thereafter the entry is canceled by the Government, the corporation is entitled, as assignee of the entryman, to repayment of the purchase money from the United States.

United States v. Colorado Anthracite Co., 32 Supreme Court Reporter, 617. May 27, 1912.

### DIRECTOR OF GEOLOGICAL SURVEY TO REPORT ON MINERAL CHARACTER OF LIEU LANDS.

"Hereafter in the matter of all railroad and state indemnity selections, state selections in satisfaction of quantity grants, forest lieu selections, and selections made by the railway company or individuals under the provisions of the Act of July 1, 1898, the Commissioner of the General Land Office will request the Director of the Geological Survey to report whether the land sought is valuable because of coal or other mineral deposits, and also whether the same has any value for power or reservoir purposes or is needed in connection with any existing or contemplated power or reservoir site withdrawal. When any such selection is sent to the Department for consideration, the report of the Geological Survey should accompany the papers, reference thereto being made in the letter of transmittal."

Instructions of the Secretary of the Interior dated Jan. 11, 1912. (Unpublished.)

## EDITORIAL

ACCORDING to the jury, Mr. Darrow didn't do it. Very well, Mr. Darrow, but don't let it happen again.

TRAVEL broadens a man. The journey of the Secretary of State to the Empire of Japan is to be commended.

**M**INING by boat is common enough in the dredging field, but mining and tramping by boat underground is distinctly unusual. Our Joplin correspondent describes this week how a scow is used in one of the sheet-ground mines of Missouri for pulling pillars without unwatering the mine.

**L**AKE SUPERIOR engineers are to hold their annual gathering at Houghton, Michigan, this year, and sessions will be held August 28, 29, and 30. The Lake Superior Mining Institute is one of the liveliest local organizations of engineers in America and its sessions are always of much more than local interest. The preliminary announcement shows that the program will be fully up to the usual standard of the Institute.

MONTANA is now in line with a request for a local mining experiment station to be conducted by the Bureau of Mines. We are glad to understand that there is small probability of any of these bills being enacted as they stand. We approve heartily of the proposed work and are well assured of the competence of the United States Bureau of Mines, but establishment of a number of fixed local stations savors too much of the pork barrel to warrant support.

**M**INING in Canada, it is said, is about to receive further recognition by the appointment of a Dominion Minister of Mines. At present the Geological Survey and the Mines Branch of the Department of Mines are under the charge of a Deputy Minister, Mr. A. P. Low. Owing to Mr. Low's long sickness, the effective direction of affairs has been for some time in the able hands of Mr. R. W. Brock, director of the Geological Survey. If a separate minister be appointed, it will give the mines direct representation in the cabinet, and in view of the great and growing importance of mining in Canada, this would be but deserved recognition.

**CIVIL ENGINEERS** in England have taken the lead in a movement to raise a fund for the purpose of placing in Westminster Abbey a memorial window in recognition of the distinguished service of Lord Kelvin as an engineer and man of science. Since the benefits of his work have been world-wide, it is especially to be hoped that the funds will come from every land. A co-operating committee consisting of Messrs. James F. Kemp, Samuel B. Christy, James Douglas, and Joseph Struthers has been appointed on behalf of the American Institute of Mining Engineers. Subscriptions of \$5 to \$10 are requested, and checks may be sent to Mr. Struthers, who is acting as chairman of the committee.

**P**EACE at any price! Such has been the watchword of the administration, and the reign of disorder, of loot, rapine, and murder, in Mexico has been suffered unmolested to pursue its riotous way. The lives and property of American citizens in Mexico have not concerned the authorities at Washington. Were not Americans warned to leave? Therefore, if they stay, they do so at their own risk. But this policy is applicable to Mexico only. The lives and property of Americans in Nicaragua are precious to the administration. The principle of 'peace at any price' does not restrain the landing of marines, accompanied with the proclamations and warnings appropriate to the case. We see the difference, but we fail to comprehend the distinction.

**S**AMPLING is at the base of any adequate estimate of tonnage and recovery, but, unfortunately, difficulties incident to variations in moisture and to the scale of modern operations, lead to provision of inadequate sampling devices at many mills. It is related that at one of the best known, where a certain recovery had been promised, cars were counted instead of weighed, and were assumed to contain 60 tons each. The promised recovery resulted. When, however, smelting returns became available there was an evident shortage of metal. The output was therefore recalculated on the basis of 50 tons to the car. This gave the promised recovery, but indicated such a shrinkage in the capacity of the mill as to provoke a protest from the designers. In the interest of harmony, therefore, a compromise figure of 55 tons to the car was assumed and a slightly lower percentage of recovery admitted. Knowledge of such conditions may have something to do with puzzling disinclination to soar shown by certain stocks.

**I**T is becoming common for railroads to prohibit employees from using liquor. The Delaware, Lackawanna & Western has gone further than others in demanding abstinence and healthy habits. Not only while on duty, but at all times, must the employee abstain, on the ground that alcohol impairs efficiency and reliability. The new regulations even require that workmen refrain from patronizing games and amusements that excite the emotions and cause loss of sleep. We recall instructions once sent by the late ex-Mayor Grace of New York to one of his mining engineers in the field: "Keep well rested; do not attempt an important piece of work when tired; and avoid all things that use up physical and nervous strength to no purpose." One of the ways to increase efficiency is unquestionably to insure nervous economy, which will soon become translated into financial economy. It is not only safety of operation that the Delaware, Lackawanna & Western, the Pennsylvania, and the Baltimore & Ohio railroads will gain by their new regulations; the result will soon be evident in a reduction of the ratio of operating cost to gross income. Mining companies may well take notice.

**C**HICAGO, long considered by many to be merely a railroad junction point where pork was packed, has become in recent years a city great not only in material wealth, but in civic ideals and accomplishments. No one familiar with her traction settlement, park system, public playgrounds, art school, orchestra, libraries, and University, no one who is prepared intelligently to contrast the present with the old Chicago, can doubt that the city is becoming great in the things that make for permanent good as well as wealth. Death of D. H. Burnham removed one of the men who contributed mightily to the new order, but the best thing about Chicago is that its betterment depends upon no one man or group of men. Mr. John D. Rockefeller did well when he gave millions to build

up a great university at this melting pot of America; but he did better when, having assured the fair starting of the institution, he withdrew and threw responsibility for its maintenance and future growth upon the local citizens. They have responded to the appeal in a characteristic Chicago manner. But a few days ago Mr. Julius Rosenwald celebrated his fiftieth birthday by giving many thousand dollars to various local institutions devoted to social betterment. Among other gifts was one of \$250,000 for new buildings at the university, and in this mining men have a special interest, since among the departments for which provision is to be made, is that of geology. With Mr. T. C. Chamberlin at the head, any department of geology would be assured of greatness, and with the men he early gathered around him, the old quarters have long been outgrown. The University of Chicago has been a powerful influence toward the development of new concepts and clear thinking in geology. We congratulate the University and the department upon the better facilities that will be afforded as a result of the gift of Mr. Rosenwald.

**B**OOMERS frequently defeat their own purpose, and that seems to be happening in the case of High Grade. We have already referred several times to the foolish stories published about this old district with a new name in Modoc county, California. There are good veins, and rich ore has been found. It is altogether probable that two or three good mines will be developed; an opinion in which we are glad to be in accord with Mr. W. H. Storms, state mineralogist, who has but recently returned from the district. There was no excuse, however, for the rush into the district when snow was so deep that location stakes were tied to tree tops in place of being driven in the ground, and there is no excuse for the stories now being circulated. Recently Mr. J. M. Hill, of the United States Geological Survey, while studying various small districts in Nevada, was instructed to examine High Grade. He had hardly got on the ground when news items were extensively circulated to the effect that the Geological Survey had found the district to be "a second Cripple Creek." This was so far from the truth that Survey officials naturally resented the attempt to misrepresent the Bureau, and Mr. Hill has now been ordered away from the district. It is proposed to defer completion of the examination until heated imaginations shall have cooled enough to permit an accurate survey to be made and a report published without being used to toll dollars from the pockets of the unwary.

**M**INING companies are becoming more liberal in issuing and publishing full reports of their operations for the benefit of the stockholders and the interested public. This is as it should be, and all such information from an authentic source can only result in the advancement of the industry. There are still some companies, however, who seem to believe that 'silence is golden,' and who steadfastly refuse to publish any information themselves, or to allow anyone to tell for them what is being accomplished at their plants. In most cases this should not be placed to the discredit of the managers and engineers in charge of operations, but rather charged against the financiers who control the property. Some men profess to believe that they can gain importance by surrounding their operations by a veil of mystery. Strict orders are accordingly issued to superintendents and foremen not to talk to outsiders, and in some instances the rule is even made to exclude all visitors. To be sure, certain justification can be found for this policy on the ground that an individual, and a corporation as well, has a right to keep business trade secrets from a too inquisitive public. Such a policy in mining, however,

is extremely selfish and short-sighted, and when it comes to research work, though common, it is exactly the policy most likely to kill invention, stifle discovery, and promote waste of funds. How many companies in the last decade have duplicated long and costly experiments already made by neighboring concerns? How much time and money has been squandered in laboratories, in mills, and in smelters by men attacking problems at the beginning and laboriously working through a mass of preliminary investigations, when as a result of a more liberal policy they might have had access to information which would have enabled them to start at the real heart of the problem? When work is being done toward the obtaining of a patent there may be some excuse for secrecy, but why should companies hesitate to publish the results of tests made with standard machines, or the results of the operation of a developed process on a certain class of ore? Some managers seem to enjoy this imposed secrecy, while others rebel and go so far as to give up occasional information to fellow engineers, but always on the assurance that it will not be published. With the changing conditions in mining and the consolidation of interests there will undoubtedly be a more liberal exchange of results among the engineers employed in the different departments of the corporations. It is to be hoped that the public and the engineers outside the circle of corporation service will at the same time receive some benefit in the form of direct information and will not always be compelled to wait on the inspired reports of stockbrokers for their news in regard to the success or failure of new methods and new plants.

### Finding Mines

It is a common remark these days that the public is not in the market for mines, and this is largely true. The reason is not far to seek. The public, meaning thereby the general and uninformed public, has received but little return from past investment and has but little reason to buy again. It was long too easy both here and abroad, to 'float off on the public' the unprofitable ventures and lock in the safe certificates in those that did well. Methods in London and Denver differed, but the game, and game it was, was essentially the same. There are those among engineers, and some rank high in ability and accomplishment, who privately, if not publicly, defend the practice. They say that the risk in mining is so great that if it were not possible to pass on to the public a large percentage of the failures, there would be no profit left for the insiders. Others point out that the West has been developed by Eastern money, much of which would not have left home save in hope of the unusual gain foretold by the fanciful tales of the promoter. The individual 'investor,' who was usually at heart a gambler, lost; but real mines were found and the West was developed. Whatever be the line of argument, however, there is general agreement that the game is now slow, and a wide fear that it has been stopped for a long period, if not permanently. It is true that large promotions do now occur, and that the public has full opportunity to invest in poor as well as good ventures. There is, however, one considerable difference. In Western America it was for many years possible for men of no real financial responsibility to take an option on a property and, by advertising, by circulars, through solicitors, and through wash sales on the minor stock exchanges, to gather the money to pay for the option, for the selling campaign, the development and plant, and finally to reserve to themselves the major share of any possible profits. This is still done, but not frequently or easily. In any large and successful mine promotion nowadays, the promoter or his backer must

usually put up actual cash in considerable amounts at some stage. Where this is not necessary it is because an established firm with several successes to its credit, underwrites the issue of stock or buys the bonds, and on this assurance of success in financing the property, the public buys so promptly that the underwriters do not need to advance money. This does not happen as often as the brokers would like the public to believe, and it is an open secret that in a number of successful ventures, where good mines are paying fair dividends, the campaign of distribution has been slow or unsuccessful. It is clear, none the less, that even at a possibly higher price per share, the present plan is advantageous to the public as compared with the old. Formerly the buyers of a few shares in a new property took all the risk of mining, plus the risk of 'thin ice' financing, and paid a heavy commission to the 'sure thing' men who manipulated the deal. Conditions are none too good now. The shares absorbed by underwriters and paid as commissions are large; but a real service is performed and a real risk is saved the public. The security to the latter is actually greater than it seems, since a promoting house saddled with a bad venture must often, if it is to maintain itself with its clients, sustain the market by buying back securities distributed with much pains and at some cost. So heavy is this tax that some of the most successful mining partnerships in America never go to the public for funds. The Hagen-Hearst partnership, which scored a number of the biggest successes in American mining, always preferred to spend money underground rather than on stock exchanges. Other men frankly accept the situation, and by gambling in stocks of established properties that they control, recoup losses on new ventures.

Business is founded on confidence. The average wage earner deposits his money in a savings bank because he has confidence in the management. He accepts a low rate of interest and the banker is thereby able to make a profit by buying bonds, in which he, in turn, has confidence. The banker takes his profit and lends personal funds on the more risky but more attractive ventures. Thus the accumulated funds of the many make possible the large profits of the few. From one point of view the division is inequitable; but systems that result from years of growth have usually much to justify themselves, and under this plan there is at each stage a margin of safety. When a promoter cuts across lots direct to the investor he may, though he seldom does, pay the latter a larger profit; but he wipes out the safeguards that normally stand between. We believe thoroughly that mining is a proper investment for funds, but we do not believe in the general peddling of mining stocks. A mining venture must be based upon knowledge, and that necessarily limits the number who may participate. We are glad to see that with the passing of the era of 10-cent shares sold on the installment plan, we are returning to the old system of mining partnerships. There are more men out now actively looking for mines and actually spending money on the ground, than there was at the height of the Cripple Creek or Goldfield booms. The demand now is for mines to work, not mines to boom and sell. With the greater skill, the closer personal direction, and the more earnest purpose of the present, the mines are being found. In the meantime promoters and claim owners, not yet alive to changed conditions, are wasting time and money 'presenting propositions' which will not stand analysis. They make statements that cannot be verified and ask prices only justified on the bases of an immediate re-sale to a waiting and crazy public. The public has a towel around its head, and with a firm grasp on the ice pitcher refuses to be interested—and the public is right.

## Persistence of Ore in Depth—I

By T. A. RICKARD

The paper on this subject presented by my friend, F. Lynwood Garrison, before the Toronto meeting of the Canadian Mining Institute, revives a useful controversy to which I made my first contribution in 1891. It is a subject of vital importance to the mining industry. The application of scientific methods of thinking is the foundation of the art of making money out of ore deposits.

Twenty years ago it was generally held, among speculators and operators in mining, that ore-bearing veins became richer in depth. Deep sinking was advocated as the most practical way of improving the chances of a mine that looked sickly in its shallow levels. The general attitude on the question is exemplified by the following quotation from a prospectus on the Phoenix mine, at Skipper's Point, New Zealand: "It has been inspected and reported upon by several eminent engineers who have declared that the quartz lodes are true fissure veins and in true fissure veins it is well known that there is no fear of giving out or not paying as depth is reached, the experience being that they get richer the farther they go down." This comes from the prospectus as published in *The Illustrated London News*, in 1892. I know the Phoenix mine, for I examined it in 1890; needless to say, I was not among "the eminent engineers" to whom reference is made. Even in those days the true-fissure idea was becoming decrepit, but the fancy lingered that 'true fissure veins' penetrated into the very heart of creation and continued rich to the unknown interior of the earth. The theory that ore was a deposit from mineral solutions welling upward from the interior had generated the notion that the nearer the mine approached the supposed source of the ore the richer it must become. Of course, "experience" had not justified the hope that veins "get richer the farther they go down," but the wish has been the father to loose thinking from time immemorial, especially in company prospectuses.

In the decade following 1883, lateral secretion, that is, enrichment of lodes by leaching of the adjacent rocks, was in the ascendant, in consequence of Sandberger's diagnosis of famous European mining regions, and the hasty exaggeration by others of the views expressed by S. F. Emmons in regard to Leadville. This checked the idea of indefinite enrichment in depth, for geologic reasoning veered the other way, but it was the work done later by Emmons himself and by W. H. Weed on secondary enrichment that gave the geologists valid grounds for controverting a popular generalization.

One of the stout defenders of the old fallacy was William P. Blake. In the *Engineering and Mining Journal* of January 7, 1893, he contributed an article on 'The Persistence of Ore in Lodes in Depth.' He confesses that "the tendency of the theories of lateral secretion seems to be to shake our faith in the full mineralization of lodes at great depths." He refers to rich ore being found in the Dolcoath mine at 2700 ft. below the surface and argues that "in this instance, as in others which may be cited, increase of depth does not show any impairment of the richness of the lode, but rather its betterment. We are not, however, justified in accepting the popular idea, or hope, that lodes grow richer in depth. We shall be satisfied if it can be shown that lodes can be expected to maintain their average value at any depths we are ever likely to reach in mining operations." He essayed to prove this in an interesting article, which ends with these words: "Whatever view we may take of the source of the mineralization of lodes, we may conclude from the evidence that it is deep-seated; and in a homogeneous country rock may be expected to extend as far as we can ever reach downward in mining operations."

The editor (Richard P. Rothwell) invited criticism on the subject. Hence in the issue of January 21, that is, two weeks later, I broke a lance with the old professor. It

was easy to point to the fact that Dolcoath, if rich just then in its deepest workings, was a solitary survivor among hundreds of mines in the same district that had become too poor to be operated at shallow levels. Taking other examples quoted by the professor, I controverted his evidence and proffered testimony to the contrary. By way of conclusion I said then: "Let us not bend facts to theories, but rather bring our theories in accord with the facts. When we do so we shall, I believe, find that ores do not, as a rule, persist in depth, much less get richer, but we shall recognize that the exceptions to this general experience are fortunately numerous."

That was 20 years ago; the dear old white-haired professor has crossed the range: his theory in turn has been relegated to one side by geologists as a "popular idea, or hope"; and my youthful assertions have been confirmed by every thousand feet the miner has penetrated the earth.

Since 1893 technical opinion has undergone a great change. The logic of facts has proved irresistible. It is only in a flamboyant prospectus or in a popular article that anybody dares now to repeat the old fallacy. With the revival of interest in the genesis of ore deposits, after the Posepny paper was published, and with the acceptance of a tentative theory of secondary enrichment, especially of copper ores, consequent upon the papers of Emmons and Weed, it became impossible for any responsible geologist to make an optimistic generalization on the subject of the indefinite persistence of bonanzas in depth. The mine-owner might still hug the delusion, but science discarded it definitely and finally.

No discussion can be conducted profitably without an understanding of the meaning of the terms employed. Definitions are a requisite preliminary. 'Persistence' here means continuity, physical extension, or prolongation in depth. 'Ore' is metal-bearing rock that will yield a profit when exploited at a given time and place. Rock that cannot be profitably exploited today is waste. Years hence it may, under better economic conditions, be exploitable profitably. Thus also the ore, or moderately rich rock, in a given decade or in a given mine may be the 'bonanza,' that is, the inordinately rich ore, of another decade or another mine. Miners habitually look for rich ore, namely, material that will yield a handsome profit. It is not usual to go deep in the pursuit of ore that leaves a scanty margin for dividends unless a good reason exists for expecting a betterment in depth. I say that it is not "usual," because sagacious persons recognize the fact that beyond the ordinary expenses entailed there are extraordinary expenses and all the accidents of industry to be set against a narrow margin of profit. The risk becomes unattractive. Persistence of ore means the continuity of ore that will not only meet the cost but will yield a surplus for dividends. Next we come to 'depth,' a term variously used, for in its essence it is comparative. In a new district, 500 ft. is deep; in an old one, 1000 ft. is shallow. But we do not use the term in the sense employed by a mechanical engineer, we use it in this discussion to convey the idea of the mining geologist. To the latter the first dividing line between the shallow and the deep zone is the water-level, with its concomitant chemical change from the oxidized to the sulphide ores. However, even this is elementary and insufficient, for while in regions of average rainfall the water-level may be at 200 or 300 ft., in arid regions it comes much nearer to surface, so that it is reached at 40 or 50 ft. The level at which water hinders mining was early recognized as marking a change in the character of the ore; this change at first connoted impoverishment because it involved refractoriness and costliness of metallurgical treatment, but later it was found to be attended in many cases, as in some copper and silver lodes, with sulphide enrichment of a most

positive nature. Still later evidence, obtained by deeper sinking, went to show that for some distance below the water-level the finding of rich sulphide ore was likely. Conditions favoring secondary enrichment might in some cases, as at Butte, continue to a depth of 2500 ft. from the surface. In gold mining the rich orebodies were found to extend far below 1000 ft., bonanzas being sometimes uncovered at twice that depth. In short, 'depth' became a term the significance of which varied locally, according not only to the amount of shaft-sinking but the geologic structure ascertained thereby. Thus the term is incapable of a definition universally applicable. It is essentially comparative. The old idea of increasing richness in depth or the modified notion of a maintenance of moderate richness persistently downward alike meant that the orebody was expected not to come to an end but to continue indefinitely deeper. No limit was set to profitable mining except the mechanical obstacles incidental to the increasing distance from the surface. During the last 20 years, however, the improvement in pumping, hoisting, and boring machinery has more than sufficed to enable man to go deeper than any orebody he has yet uncovered. At one time several of us argued against the probability of indefinite persistence or increasing richness in depth. Now we deny it—as a generalization—confidently. A tragedy has supervened: a lovely theory has been killed by a number of ugly facts.

Those who made their wish the father to their thought had not the courage of conviction. Obviously, if lodes generally become richer in depth, their system of mining was all wrong. If an orebody is confidently believed to extend 5000 ft., for example, it is absurd to sink a hundred feet at a time and stope the ground overhead; this would be what a Cornishman calls "pulling out the h'ore by the 'air of the 'ead." As compared to a bolder and more comprehensive scheme, it is underhand stoping and winzing. A good miner who knew that his orebody reached to 5000 ft. would sink a main shaft to the bottom of the ore and open up the mine in a big way. Of course, the capital required would be greater and the return upon it would be delayed; but that would be no obstacle to enterprising men if it assured richer ore and a constant supply of it to a mill of heroic proportions. Moreover, the dangers and difficulties that befall every big and deep mine by reason of the caving of ground due to the ever-increasing pressure of the hanging-wall country upon the old workings would be obviated by excavating from the bottom upward. There would always be a thick arch to protect the stopes, and that arch would become weakened in proportion as its burden became less dangerous. No; the experienced miner may echo the loose optimism of the promoter or the make-believe of the speculator; but he knows better. He follows the ore from surface, never knowing when it may thin to a thread; he takes short views of geologic continuity; he proves his mine before he builds his mill.

Man has never failed to go deeper than the orebodies he has found. The Comstock, the copper lodes of Luke Superior, the saddle-reefs of Bendigo, the veins of Przibram are usually considered to typify the most profound search for the valuable metals. The Adalbert shaft at Przibram, in Bohemia, attained a depth of 3600 ft. below the surface and 1850 ft. below the sea-level. It was highly productive for a long time, but it is now idle, because it became unprofitable to continue mining operations. The Cambrian sandstone in which the rich ore was found is succeeded in the hanging wall of the deeper workings by pre-Cambrian slate, but the origin of the ore is associated with dikes of diorite. The ore in the deepest workings shows the same structure as in the upper levels; only it is less rich.

The Comstock was once synonymous with a natural treasure-vault, yet its bonanzas were found at a relatively shallow horizon. The big bonanzas of the California and Virginia mines reached from 1100 to 1860 ft. The most productive portion of the Comstock mines was above the level of the Sutro tunnel, which cuts the lode at about 1850 ft. below the outcrop. The Combination shaft was sunk to a vertical depth of 3260 ft. Later workings from the Union

shaft went down to 3350 ft., but they found only patches of rich ore. Broadly speaking, mining became unprofitable in depth, not because of hot water or other physical obstacles, but just because rich ore was less plentiful and barren rock was more abundant.

The deepest metal mine in the world is the Tamarack, at Calumet, Michigan. This mine is the 'deep-level' of the Calumet & Hecla, that is, it gets the lode on its dip after it passes out of the vertical side-line of the Calumet & Hecla property. The No. 1 shaft of the Tamarack cut the Calumet conglomerate lode at 2270 ft. and the Osceola amygdaloid lode at 1000 ft. deeper. The No. 5 shaft, which is 5253 ft. deep, cut the Calumet lode at 4835 ft., and the No. 3, which is 5281 ft. deep, cut it at 4662 ft. The deepest workings in any metal mine are those of the No. 5 shaft, for they extend to 5368 ft. vertically below the surface. The Red Jacket shaft of the Calumet & Hecla cuts the same lode at 3287 ft. and was sunk at 4920 ft. In 1901 it was recognized that the wonderful run of ore had been bottomed. The yield of copper in the Calumet & Hecla declined from 5% in 1873 to 3% in 1900, and 1½% in 1910. The Tamarack venture was a disappointment, for it was based on the expectation of persistent ore. The Tamarack paid its last dividend in 1907 and was absorbed by the Calumet & Hecla in 1911. The future of the Calumet & Hecla company depends not on its own deep workings but the yield from shallower subsidiary mines.

The 180 mine at Bendigo was, for many years, the deepest gold mine in the world. After it ceased to be the deepest, other mines in the same district maintained the tradition for profitable work at a greater depth. It was more a tradition than a fact. The maximum depth attained at Bendigo is in the Victoria Reef Quartz mine, which has a shaft that has been sunk to 4614 ft. A saddle formation cut in the neighboring New Chum Railway mine at 4154 ft. induced the further exploration of the same orebody, which, on its pitch, would enter the Victoria Reef Quartz claim at 4800 ft. But the undertaking was never completed because the representatives of the Lansell estate, the chief shareholder, withdrew financial support, despite a subsidy subscribed by the Mining Department of Victoria. In the New Chum Railway the orebody averaged 6½ dwt. per ton, a yield quite insufficient to compensate for all the expenditure incurred in sinking and cross-cutting before stoping could actually begin. Now all the deep mines on the New Chum line have ceased operations and work has been diverted to prospecting the shallower ground, incompletely tested at a time when the fashion was to sink deeper in the vain hope of finding richer ore. When I was at Bendigo first, in 1890, it was held that any mine in unproductive ground needed only to be deepened to return to the dividend list. Up to a certain point deep sinking proved sagacious, but that was at a horizon far above the ultimate depth attained. I doubt whether mining at Bendigo on the whole was profitable below 2000 ft. Some mines were temporarily profitable, but allowing for the unsuccessful properties and for the expense incurred even by the successful ones in their search, I question whether money was made below 2000 ft., which is less than one-half the total depth attained in this celebrated district. I ventured to express my own doubts in regard to the deep-sinking craze in 1890, and then advocated lateral exploration on intermediate 'lines of reef,' as the anticlinal lode-channels are named locally. Now the mine managers are of the same opinion, for *The Bendigo Advertiser*,\* the exponent of local industry, speaks of the vindication of the "shallow ground" theory, and proceeds to say: "In almost every, if not in every, gold mining area in the world the experience is that as considerable depths are attained, the gold is scarcer. The depositions of quartz may be more or less or practically the same as in the upper levels. Opinions vary on that point, but most authorities agree that as the earth is penetrated to great depths gold is less plentiful. Bendigo investors and speculators know from

\*June 10, 1912.

bitter experience the absolute truth of the latter point, as far as this field is concerned." This is interesting, especially to one who remembers the confident optimism of a bygone day. The editor of the *Advertiser* may not be a scientific man, but his frank submission to the logic of facts is deeply significant, for he expresses the opinions prevalent among the most intelligent of the mine managers at Bendigo. No local mining paper would have dared to talk in this strain twenty years ago.

## The Great Cobar Copper Mine

One of the excursions of the annual meeting of the Australasian Institute of Mining Engineers was to the above mine and smelting plant on June 1 and 2; and the *Mining and Engineering Review* of July 5 gives an interesting résumé of the company's property. H. C. Bellinger, general manager for the Cobar company, is the president of the Australasian Institute of Mining Engineers, and the visiting engineers had an instructive and pleasant time at Cobar.

The Great Cobar property comprises a group of four mines, three of which have been purchased during recent years. The lodes of the Cobar district occur along a narrow belt of Silurian rocks, some 20 miles long, which is flanked both east and west by Devonian quartzites and slates. Both the Silurian and Devonian rocks have been intensely folded, and strike about 17° west. No lodes occur in the Devonian, and those in the Silurian are lens-shaped in horizontal section. At the 1200 and 1400-ft. levels of the Great Cobar mine, the orebodies keep their size. The ores consist of iron pyrite, copper pyrite, pyrrhotite, magnetite, and galena. There is an absence of outcrops of igneous rocks at Cobar. The main shaft, 15 by 8 ft., is down 1400 ft., and is equipped with a hoist having cylinders 22 by 48 in., drums 10 ft. diameter and capable of lifting a 2-ton load at 2000 ft. per minute. The steel head-gear is 67 ft. high. The ore reserves in the mines are as follows:

Mine.	Tonnage.	Copper, %.	Gold, dwt.
Great Cobar .....	2,000,000	2.6	1
Cobar Gold .....	350,000	1.5	10
Chesney .....	750,000	2.7	1
Peak .....	Development on lode to prove reserves.		

The parent mine has three great lenses of ore, which are about 70 by 450 ft. in the centre lens, 90 by 300 ft. in the north lens, and 50 by 150 ft. in the south lens. These lenses are separated from one another by fair widths of mineralized slate.

Previous to being bought by the Great Cobar, the Cobar Gold, and Chesney were worked as gold mines, and treated their ores in stamp-mills, but the ore became too refractory for such treatment. Now the output from the group is smelted. The cars of ore from the shaft cages are emptied into a storage-bin holding 450 tons, by a rotary tippie. The ore is broken by two Hadfield gyratory crushers, then passes over picking belts to the bedding pits. From these it is put into cars, a small portion from each being kept in a special car, which, when full, is sent to the sampling mill. This mill includes a Babcock & Wilcox tray conveyor having a capacity of 50 tons per hour, at 45 ft. per minute, which delivers the ore to a similar conveyor set at an angle of 20°. This feeds a No. 5 McGully breaker, and a 15% cut of the broken ore is made by a 64-in. Simplex sampler. After a No. 3 McGully breaker, a 20% cut is made by a 44-in. machine. Rolls, 24 by 14 in., further crush the sample, and a 28-in. machine takes a 15% cut. After another set of rolls, 24 by 14 in., another 15% cut is made, the final samples going to a sample grinder.

The smelter consists of four blast-furnaces, each 56 by 240 in., with a total capacity of 200 tons daily, the present average being 1250 tons. The furnace charge is approximately four parts of Great Cobar ore to one of sili-

cious ore from the other mines mentioned. No furnace slag is used in the charge, excepting that from the converters. There are two tiers of water-jackets, 4 by 10 ft., and there are 40 tuyeres supplied by a 34-in. bustle pipe. The furnaces are 8.5 ft. from ground to tapping-floor; 26.5 ft. from tapping to charging-floor; 50.25 ft. from charging floor to top of the auxiliary stack; and 19.5 ft. from top of superstructure to down-take. The furnace charge-cars have capacities of 34 and 44 cu. ft. There is a continuous discharge from the furnaces to the forehearths, 4.5 ft. by 9.5 ft. The slag flows into Berg and Dewhurst slag ladles of 200 and 280 cu. ft. capacity, and is taken to the dump. The converters are of the barrel type, 84 by 126 in., with 14 tuyeres, and are handled by two 40-ton Babcock & Wilcox overhead cranes. The power-plant contains 6 Babcock boilers of 3580 sq. ft. heating surface, fitted with stokers and superheaters. Three Brownell-Lindley triple-expansion engines of 250 hp. each are direct-connected to Siemens generators, for general power purposes. The furnace blast is supplied by four Morley engines coupled to two Connorsville blowers, 48 by 78 by 96 in., having a capacity of 36,000 cu. ft. of air at 42 oz. pressure. The converters are supplied by a Walker Bros. compressor, supplying 9000 cu. ft. at 36 to 48 oz. pressure.

Costs per ton are: Mining, \$2.26; smelting, \$1.78; converting, \$0.42; total, \$4.46.

In 1911 the Great Cobar property treated 346,303 tons of ore yielding 6548 tons of blister copper, valued at \$1,830,000. The total production of copper since 1876 amounts to 89,009 tons.

## Mining in Quebec in 1911

According to the returns received by the Quebec Mines Branch from the producers, the mineral production of the province during the year 1911 reached a total value of \$8,679,786, an increase of \$1,356,505 on the previous year. By the addition of Ungava the area of Quebec is now 708,000 square miles, offering great scope for prospecting. Railways already and will increasingly render accessible northern parts of the province. There were no changes or amendments in the mining law during the past session of the provincial legislature. Two field parties were sent out by the Mines Branch during the year, one mapping out the geology of an area in the vicinity of Kewagama lake, south of the National Transcontinental railway, while the other party began an investigation of the iron resources of the state, with special reference to the deposits of titaniferous ores. The report of the Mines Department gives details of mining of various minerals, and contains reports on the following: 'Accidents in Mines,' by J. H. Valiquette. There were 7846 men at work, the fatal rate being 0.77 per 1000 employed. 'Report on the Montreal Quarries,' by J. H. Valiquette; 'Preliminary Report on Some Iron Deposits on the North Shore of the River and Gulf of St. Lawrence,' by E. Dulieux; 'The Magnetic Sands of the North Shore of the Gulf of St. Lawrence,' by the same writer; and 'Report on the Geology and Mineral Resources of Keekeek and Kewagama Lakes Region,' by J. A. Bancroft. The papers are well illustrated with maps and half-tones. The most important mineral products from Quebec in 1911 are as under:

	Value.
Asbestos, tons .....	102,224 \$3,026,306
Cement, bbl. ....	1,588,283 1,931,183
Bricks, number .....	176,532,000 1,129,480
Limestone .....	1,128,402 308,545
Granite .....	284,334
Lime, bushels .....	1,284,914 240,097
Copper and sulphur ores, tons..	38,554 76,428
Mica, pounds .....	590 11,800
Gold, ounces .....	23,000 11,500
Silver, ounces .....	

Besides the above, there were fair quantities of many other minerals produced.

# Mines of the Republic District, Washington

By SIDNEY NORMAN

Unless all present signs fail, the gold camp of Republic, Ferry county, Washington, which passed through a 'boom' 12 years ago and subsequent abandonment of operations, will soon become as popular as it was in the earlier days. From a pessimistic community of but a few hundred souls five years ago, Republic has grown to a prosperous thriving town of perhaps 2000 population, while new arrivals are in evidence daily, and the residential facilities of the town are taxed to their utmost.

The resurrection of the camp dates from about four years ago, when J. L. Harper, who had been operating at Belcher, secured control of the old Republic group from

REPUBLIC, WASHINGTON, FROM THE NORTH.

ranks of the stockholders of the New Republic Mining Co., which had been organized by Mr. Harper, the net result being his retirement and the subsequent haphazard development of the ground. Later it passed to the Rathfone Reduction Co., which erected a cyanide plant for the treatment of the old tailing pile, and met with some success. The property is not now being worked, but it is understood that engineers have just concluded an exhaustive examination of the old workings with the idea of consolidating the New Republic, Rathfone Reduction, and Princes Republic companies. Should such plan be consummated, the Rathfone plant will be brought up to greater capacity by the addition of adequate crushing machinery, thus giving to the camp three plants fully equipped for the reduction of its ores.

After severing his connection with the New Republic, Mr. Harper turned his attention to the Lone Pine, the Surprise, and adjacent ground on the east side of Eureka gulch. Working bonds were secured, and the development of the ground undertaken. Since that time 46,734 tons has been sent forward to the Granby and Trail smelters, of an average value approximating \$22, and the total value has been \$1,067,603 gross. During last March 1841 tons was shipped averaging \$21.26 per ton, while in April the output was 2475 tons, averaging \$17.63. The first 862 tons shipped in May gave smelter returns of \$17,364, or an average of \$20.13 per ton. These are the latest figures available, but the probabilities are that the shipments since then have been of higher value, owing to the discovery of a large high-grade orebody near the point where the 670-ft. incline shaft passed through the vein. A winze

MILL OF THE SANS POIL CON. CO., FROM NO. 2 DUMP.

the county, to which it had reverted for unpaid taxes. Just previous to the transfer the property had been leased by the county to a partnership of miners which included James Casey, formerly superintendent under the Patrick Clark regime, and several high-grade shoots had been found and ore shipped from the old workings. Within a short time after Mr. Harper assumed control, a different aspect had been placed upon the property, and dividends amounting to \$35,000 were subsequently paid. From that time forward public interest in the district revived, though the residents of Spokane, who had financed a large majority of operations in the early days, still looked with skepticism upon the movement. Money supplied by the farmers of the Palouse country has been largely responsible for the revival, and particular credit is due to T. A. White, of Colfax, who helped to finance the early operations of Mr. Harper.

A little more than two years ago dissension arose in the

is being sunk on this shoot and was down 75 ft. on June 10. At that time it showed a full bottom of quartz, and daily mine samples from June 7 to 11 gave a general gross average of \$59 per ton. No returns from the smelter are yet available on this particular shoot, but mine assays or carload shipments have run around \$35 per ton.

The extraction of this large tonnage of high-grade ore necessarily exposed larger bodies of ore that could only be economically treated by modern milling methods. Consequently Mr. Harper organized the North Washington Power & Reduction Co., with the eventual purpose of constructing a 1000-ton cyanide plant to treat ores of the Republic Corporation and custom ores. The first building was constructed to house machinery for two units of 125 tons capacity each, and the first of these units was placed in operation in May, under the management of Harry W. Newton, formerly connected with the Gold Road mine, Mohave county, Arizona. No close estimate of sav-

ing has yet been made, but it is the general opinion of mining engineers who have visited the plant that the problem of economical extraction has been solved.

The new plant occupies a site on the west side of Granite creek, within a quarter mile of the abandoned plant of the old Republic Gold Mining Co., erected in 1900 by D. C. Jackling. It is served by the Great Northern railroad from a spur running above the ore-bin level, and from this point the ore is trammed to crusher-bins, from which it is fed by a shaking-grizzly, with bars spaced at  $1\frac{1}{2}$  in., to a 20 by 10 Blake crusher. The product then goes to an 8 by 12 Dodge crusher and through 30 by 14 rolls to a belt-conveyor which carries it above the mill-bins to a Vezin sampler. From the mill-bins the product goes to a 6-ft. Trent Chilean mill, where it is ground to 16-mesh in cyanide solution. All material of 200-mesh overflows to the Trent agitator, the overflow going to a 22 by 5-ft. tube-mill. The tube-mill product is returned to an Akin classifier, where any not passing 200-mesh is again returned, the finished product flowing to the Trent agitator. In the first Trent agitator the pulp is thickened to the proper consistence for agitation and passed on to agitator No. 2. The overflow solution from No. 1 is returned continuously to the Chilean mill by a 2-in. centrifugal pump. The agitators, four in number, are connected in series for continuous agitation, the pulp passing from one to another by displacement. Thence the product flows to a 16-ft. Oliver continuous filter and the solution is pumped to clarifying tanks. The clear solution flows to the gold-tank and from there is fed to Trent precipitation tanks automatically fed with zinc-dust. The treated solution is pumped by a 6 by 8 Goulds triplex pump to the refinery above the mill.

Another reduction plant of 'resurrected' Republic is that of the Sans Poil Consolidated Mining Co., which acquired the Sans Poil and adjacent ground from Finch & Campbell about two years ago. Development carried on since that time has exposed large bodies of milling ore, while shipments aggregating 3300 tons, of a value of \$18 per ton and a total value of \$59,511, have meanwhile been sent forward. To treat this milling ore, and part of the product of the Knob Hill mine to the northeast, a 125-ton plant has been erected on the Sans Poil claim on the west side of Eureka gulch and about one mile to the north of the plant of the North Washington Power & Reduction Co. The machinery was turned over for the first time on June 8 and everything is now ready for the initial run as soon as track facilities at the ore-bin level have been provided by the Great Northern railroad. To prevent any delay in delivery of ore, the company has also undertaken the construction of a cable tramway that will haul mine-cars to the ore-bin level. The entire plant was designed by the Hammond Manufacturing Co. and has been erected under the superintendence of E. J. Morris. The main building is 90 by 100 ft., and rests on concrete foundations, as do as well all tanks and crushing machinery.

The mill design closely follows the Grass Valley type of continuous cyanide treatment, though novel crushing machinery has been introduced in the shape of a Williams hammer trommel mill, closely resembling the Quenner mill, used with such success in the Altar dry-placer fields of Sonora, Mexico, some years ago. An exact duplicate of the mill has been in use for the past year at the United States Government work on the Celilo canal near The Dalles, Oregon. There it is said to have been eminently satisfactory with a record of 20 tons crushed in one hour from coarse feed to  $\frac{1}{4}$ -mesh. A practical test, in my presence, on mine-run ore from the Sans Poil, resulted in the crushing of 1000 lb. to  $\frac{3}{16}$  inch in exactly two minutes, or at the rate of 15 tons an hour, or 120 tons in a shift of 8 hours. Feeding was done by hand, and the engine was not speeded up to capacity until the last few seconds of the run. If the mill can hold up to this test in daily work, it will provide sufficient feed for a 24-hr. run in one shift of 8 hours. Such a result would completely solve the problem of economical coarse-crush-

ing; particularly when it is remembered that a large portion of the product is converted to a fine powder in the process. The product of the Williams mill is delivered by worm-conveyor to an elevator boot that raises it to a storage bin, an automatic sample being taken on the way. Thence the product goes to a set of fine-crushing rolls, and from there it is passed on to a 5 by 12 Gates tube-mill, where it is ground to slime in cyanide solution. The discharge from the tube-mill is elevated by a tailing wheel to a duplex Dorr classifier, where a separation is made of coarse and fine material. The fine material passes to a 24-ft. diameter by 10-ft. deep Dorr thickener, and the coarse is returned to the tube-mill.

The thickened material from the bottom of the Dorr thickener passes by gravity through 10 cone-bottom air-lift agitators, connected in series and allowing sufficient contact with the cyanide to dissolve all soluble gold. The clear solution is returned to two battery-tanks for classifying purposes, the discharge from the agitation tanks flowing to a 16-ft. Oliver continuous filter of 125-ton daily capacity. The tailing is sluiced to the flat below the mill, and the solution delivered to four clarifying tanks for precipitation in twenty-four 18 by 24-in. iron zinc-boxes. Water supply is obtained from a well in the gulch and elevated to the mill by an electrically-driven power pump. Power is supplied by two boilers of 110 hp. each and a 200-hp. Erie automatic centre-crank engine. Agitation is maintained by a 10 by 16 by 10 steam-power compressor.

The Knob Hill company, largely financed by farmers of the Palouse country, is another concern that has met with success since the revival began. Its property consists of the Knob Hill and Mud Lake claims at the head of Eureka gulch, just northeast of the Sans Poil, and acquired from Jonathan Bourne of Portland, Oregon, on a bond of \$125,000, with a 25% royalty applying on the bond. From this source the sum of \$46,373 has already been credited on the bond, and further payments of \$35,000 have also been made. Dividends to the extent of \$45,000 have been declared, and sufficient is now on hand to warrant the assumption that distributions to stockholders will be maintained. Within about twenty months the company has shipped 8594 tons to smelters with a gross value of \$277,687, or an average of \$32.31 per ton. The highest consignment in that period was 47 tons, sent forward in May of last year, which yielded \$6058 gross, or an average of \$129 per ton. In extraction of this higher-grade ore large bodies of good milling ore have been uncovered, and for the present 50 tons will be sent forth daily to be treated in the Sans Poil mill. If the latter demonstrates its efficiency, the company will then undertake the erection of its own plant.

Several other properties well known in the earlier history of the camp, including the Morning Glory, Blacktail, Insurgent, Butte & Boston, Quilp, and others, are being worked in some degree, the payroll for May showing a total of 364 miners and surface men employed in the district. The Mountain Lion, Tom Thumb, and Rebate, all lying to the north of the main zone of activity, are at present idle, but in each case are rumors of impending sales that may result in resumption of operation before the summer is over.

The prime necessity of the district at this time is cheap power, and it is said that such arrangements are in a fair way to be perfected by Mr. Harper, of the Republic Mines Corporation and North Washington Power & Reduction Co. If plans mature, a high-power line will be constructed to Danville, 28 miles east, where connection will be made with the lines of the West Kootenay Power Co., owning a hydro-electric plant of great capacity at Bonington Falls, below Nelson, British Columbia, on the Kootenay river. Estimates of cost run from \$50 to \$60 per horsepower-year when such plant is in operation, and it is believed that present milling costs of around \$3 will thereby be cut at least one dollar. Coal at \$6.70 per ton, shipped from Crow's Nest is now used to generate power.

Mines of the Globe-Miami District

By F. C. CALKINS

The copper mines of the Globe-Miami district, Gila county, Arizona, are producing copper at the rate of nearly 60,000,000 lb. per year, most of this production coming from two mines, the Old Dominion at Globe, and the Miami mine near the town of Miami. When improvements now being made at these mines are finished, and development and construction work at the Inspiration Consolidated mine at Miami is completed, and that mine placed on a producing basis, the annual production of the district will be not far from 140,000,000 lb. of copper, or over 10% of the production of the United States. The three large and important mines of the Globe-Miami district are the Old Dominion, the Miami, and the Inspiration Consolidated.

PRINCIPAL GROUPS OF CLAIMS AT MIAMI.

The economic history of the district and of the Old Dominion mine dates from the year 1874, when a band of prospectors, braving the hostile Apaches, crossed the Pinal mountains from the west and located the Globe claim of what is now the Old Dominion mine. Other locations rapidly followed, and several small settlements were established, and during the next few years many claims were producing high-grade silver ore. With the decline of silver, attention was turned to the mining of copper, as there were numerous surface indications. In 1881 the Old Dominion company was operating a small furnace about one mile west of what is now the town of Miami, on copper silicate ore from a small vein in the schist nearby, but this proved unprofitable, and the smelter was moved to Globe, the Globe mine was purchased, and in 1884 two 30-ton furnaces were in operation. Since that time the mine has passed through several periods of idleness and reorganization, having changed hands several times, but has been a steady producer since the advent of the railroad in 1898, and a dividend-payer since 1907. In that year the Miami orebody was discovered in a belt of mineralized schist five miles due west of Globe, and the next five years was a period of wonderful development, during which the Miami Copper Co., the Inspiration Copper Co., the New Keystone Copper Co., and the Live Oak Development Co. proved up, by underground work and churn-drilling, the third largest deposit of copper ore in the United States, it being exceeded in size by only the Utah Copper and the Ray Consolidated deposits. Four mines have been developed on what is virtually a single ore deposit which contains several breaks and barren patches, but is over two miles long and has a maximum width of 1500 ft. The ore occurs as disseminated chalcocite in silicified schist near its contact with granite porphyry. In some places the ore extends into the porphyry. A new mining district has been created in which over 1600 men

are employed, and the number is steadily increasing. The town of Miami has a population of 2000, and the population of the Miami district is estimated to be about 4500. The population of Globe has increased from 1500 in 1902 to over 7000, according to the 1910 census. Chalcocite was disclosed by adits on the Inspiration claims as early as 1902, yet it was not found in commercial quantities, and the discovery of the immense deposit really occurred on April 13, 1907, when No. 2 shaft of the General Development Co. entered 4% ore at a depth of 225 ft. By the spring of 1909 three other companies had been organized and were exploring and developing the mineralized schist belt, and by the end of 1911 over 65,000,000 tons of ore had been proved. Following is a list of the developed ore reserves according to the latest official reports:

Mine.	Tons Ore.	Copper, %.
Miami .....	18,000,000	2.58
Keystone .....	2,500,000	2.25
Inspiration .....	30,000,000	1.95
Live Oak .....	15,000,000	2.10
Inspiration Consolidated .....	45,000,000	2.00
Total .....	65,500,000	2.17

The Old Dominion Copper M. & S. Co., which also owns the United Globe mines, produced in 1911 about 26,500,000 lb. of copper at a cost of a little over 9c. per lb. Of this, about 19,000,000 lb. was derived from ore from the Old Dominion mine and the rest from United Globe and custom ores. The ore is of two classes: oxidized ore, averaging 7.75% copper, which is directly smelted, and sulphide ore, averaging 3.5% copper, which is first concentrated. Improvements of plants and mining equipment are continually being made, and \$500,000 has been appropriated to be expended on new construction and equipment during the next two years. One of the most notable improvements now being made is the lining of the 2-compartment Kingdon shaft with concrete, which has been completed for a depth of 870 ft., with 130 ft. more to be lined. A separate flue and dust-chamber has just been built at the converter plant and a new converter-stand has been ordered which will replace the three now in use. Thereafter basic instead of acid lining will be used. Plans are being made for enlarging and doubling the capacity of the 500-ton concentrator and for equipping the shaft for hoisting ore in skips instead of cages.

It is estimated that when the above improvements are completed, the annual production will have been increased to about 30,000,000 lb. The mine is essentially a vein mine, and, owing to the large amount of water encountered and the heavy nature of the ground, it is impossible to block out ore very far in advance of mining, but the mine is said to have more ore in sight than at any time in its history, and it is believed that it will be a producer for many years to come. The deepest workings are only 1200 ft., and there remains much ground to be explored. About 1200 men are employed. G. H. Dowell is general manager, George Kingdon, mine superintendent, and L. O. Howard, superintendent of the mill and smelter.

Late in the year 1906, Fred Alsdorf, a mining engineer, and F. J. Elliot, a lawyer of Globe, secured an option on the mining claims that have since been developed into the Miami mine. J. Parke Channing was in Globe at the time, negotiating for the Inspiration claims, which he finally refused to consider on account of the excessive price asked, and after an examination of the Miami ground, acquired the option for the General Development Co., a Lewisohn corporation. Work was started on December 8, 1906, with Mr. Alsdorf in charge. Late in February

1907 the Red Rock, or No. 2 shaft, was 195 ft. deep, with no sign of ore, and the Captain, or No. 1 shaft, had disclosed only 70 ft. of 2% ore, and it was decided to cut a 20-ft. sump and then cross-cut into the hill. At the bottom of the sump the formation began to look a little better. Mr. Alsord continued sinking on his own responsibility, and in 10 ft. more, or a depth of 225 ft., the shaft went into chalcocite ore assaying 4% copper. The shaft was continued and ultimately reached the 720-ft. level, being continually in ore to a depth of 710 ft., giving a total vertical depth of 485 ft. of ore. In November 1907 the Miami copper Co. was organized, and the development of the mine, mostly by underground work and partly by churn-drilling, proceeded rapidly. By the end of 1910 there had been developed 18,000,000 tons of ore averaging 2.58% copper, and a 3000-ton concentrator, power-plant, and pumping station had been completed. On March 15, 1911, the first unit of the concentrator was started and by February 23, 1912, all six units were in full operation. The mine is now producing about 2,700,000 lb. of copper per month at a cost of about 9c. per pound, and one dividend has already been declared. The concentrator, designed by H. Kenyon Burch, is declared to be one of the best in the world, and when improvements now being made in the crushing machinery are completed, production is expected to be at the rate of 3,000,000 lb. per month. Diamond-drilling is disclosing ore below the 570-ft. level that was never included in the estimate of 18,000,000 tons, and it is conservatively estimated that at least 4,000,000 tons more will be developed. In addition to this, there is being developed by churn-drills, on the northeastern part of the property, a large body of ore averaging from 1 to 1.25% copper, which, while not now of commercial grade, will some day undoubtedly be mined at a profit. The mine is opened up by 27 miles of drifts and raises, and this figure is being added to by a mile per month. About 900 men are employed about the mine and concentrator. The concentrate is at present smelted at Cananea, Sonora, Mexico. J. Parke Channing is vice-president and consulting engineer, B. B. Gottsberger general manager, N. O. Lawton mine superintendent, and F. W. Solomon superintendent of the concentrator.

Encouraged by the success of the Miami Copper Co., William B. Thompson, of the Gunn-Thompson company, acquired the Inspiration claims and promoted the Inspiration Copper Co. in December 1908. Development was started in February 1909. Henry Krumb was the consulting engineer. At about the same time, H. B. Hovland and Hoval A. Smith secured the Live Oak mine, which had formerly produced about \$600,000 worth of copper-silicate smelting ore, and organized the Live Oak Development Co., starting work early in 1909. Development of both mines was conducted partly by underground work, but mostly by churn-drilling, and by the end of 1911 there had been developed at the two mines a total of 45,000,000 tons of ore averaging 2% copper. Near the close of that year John D. Ryan and associates bought control of the Live Oak company, and in January 1912 effected its merger with the Inspiration company, forming the Inspiration Consolidated Copper Co. with a capitalization of \$30,000,000. A period of active development and construction work has been begun that will involve the vast expenditure of \$7,000,000 in the next two years. Three development and two main working shafts are being sunk and the first haulage level is being opened. Many miles of drifts and raises will be driven to bring the mine to the point of production. Plans are being drawn for a 7500-ton concentrator, power-plant, necessary railroads, shops, etc., and construction is expected to begin in about a month. A water-supply dam has been built across Pinal creek and a pumping plant is being erected. About 600 men are employed and the number is steadily increasing. It is estimated that the mine will be able to produce 70,000,000 lb. of copper per year. Charles E. Mills is general manager, L. D. Ricketts consulting engineer, and T. R. Drummond superintendent of the Inspiration mine.

Following the development of these orebodies a number of companies have acquired claims for prospecting purposes. The Southwestern Miami Development Co. is exploring by churn-drilling a group of claims lying to the southwest of and adjoining the Live Oak mine. The Live Oak orebody apparently continues into this property and three holes have penetrated chalcocite-bearing schist. One of these holes is reported to have disclosed commercial ore. Four other holes are now being drilled as rapidly as possible. The South Live Oak Development Co. is exploring with a churn-drill the Schultze group of claims about a mile southwest of the Live Oak mine, but has not yet discovered ore. The most important mines near Globe, in the prospect stage of development are the Arizona Commercial, Iron Cap, and Superior & Boston. Arizona Commercial, which adjoins the Gray mine of the United Globe, is preparing to sink 1000 ft. to develop the extension of the Old Dominion vein. The shaft is already down 800 ft. and is being enlarged to three compartments. The Iron Cap mine adjoins the Arizona Commercial, and its equipment is being overhauled preparatory to resuming work on the sixth level. The Superior & Boston adjoins the Arizona Commercial and is developing on the twelfth level. Shipments of ore are being made from the upper levels.

Many other prospects are being worked in a small way, some of them for gold ore. The Duquesne mine has been making irregular shipments of gold-lead ore. The Gibson mine, seven miles west of Miami, is a famous small producer of high-grade copper ore, being credited with a total production to date of about 6,000,000 lb. of copper, and is now shipping about three cars per month of 16% ore. The Black Warrior mine, now idle, has produced about 15,000,000 lb. of copper in the form of copper silicate ore. About eight miles northeast of Globe the old McMorris mine, a famous producer of silver in the early eighties, is being reopened by the White-Metal Development Co., and the 800-ft. shaft has been retimbered to a depth of 200 feet.

The towns of Globe and Miami are situated on the Arizona Eastern railroad, a branch of the Southern Pacific, which joins the main line at Bowie 125 miles southeast of Globe. Miami is ten miles by rail west of Globe, and is the terminus of the line. Globe is pleasantly situated on the Globe hills along Pinal creek, at an elevation of 3500 ft., with the Pinal mountains rising to an elevation of 8000 ft. eight miles to the southwest. It is the county seat of Gila county and has a population of over 7000 inhabitants. Miami is five miles due west of Globe, near the Miami mine and at the base of the foothills of the Pinal mountains. The town was founded in October 1909 and now has a population of about 2000, which number is rapidly increasing. Many new buildings are going up and most of the business blocks are being built of concrete.

The Globe-Miami district is pre-eminently for copper production, although there is a small output of gold and silver, most of which comes from the Old Dominion mine. Production is now at the rate of nearly 60,000,000 lb. of copper per year and should be at the rate of 140,000,000 lb. within three years. At present Miami concentrate is shipped to Cananea, as the Old Dominion smelter is not equipped for smelting it. It is believed that a new smelter will be built in the district to handle the concentrates from the various mines. About 3000 men are employed about the smelter, concentrators, and mines, and the total population is estimated at about 12,000. The miners are mostly southern European races and the minimum wages are \$3.50 for eight hours work. The mines at Miami have an assured life of at least twenty years and the district will probably be producing copper after the present generation of miners has drawn its last pay check.

DEATH RATE due to accidents on Rand gold mines in 1911 was 3.57 per 1000 whites, and 4.02 per 1000 colored workers, while the death rate due to disease among all Transvaal mine employees was 12.89 per 1000 whites and 28.85 per 1000 natives.

## Improvements at Ashio Mines and Mills

By H. FOSTER BAIN

Among the mines visited by the American engineers who traveled through Japan last year was the Ashio, the leading copper producer of the Empire. This mine has already been described in the *Mining and Scientific Press* (October 14, 1911) by Thomas T. Read. I propose merely to present here supplementary data gathered at the time of my visit or supplied since through the courtesy of the engineers of the Furukawa Mining Co., the owning corporation.

The Ashio mine, of which K. Inouye is manager, produced 16,964,227 lb. of copper in 1911, an increase of 1,332,901 lb. over the output for 1910, and thereby maintained its position at the head of Japanese copper mines. Since new workings and new dressing plants are constantly being added, and some of the most extensive improvements had not been completed at the end of 1911, the production may be expected to continue to increase for several years. While pressed close by the Sumitomo and Fujita companies, the Furukawa company is the leading copper concern in the Far East. It now manufactures about 1000 tons of copper wire per month and is an extensive buyer as well as miner of ore. In Japan the era of trolley cars has just begun. Interurbans are operated between Yokohama and Tokyo and local lines in all the principal cities. In a country of dense population, abundant water-power, and mountainous topography, it takes no prophet to see a rapid extension of electric lines. This is all the more probable since in many parts of the Empire railway lines even yet fail to reach important towns. With no vested interests to overcome, the trolley magnate should thrive. The Furukawa company is not, however, looking to the local demand alone, but is already preparing to enter the markets of India and Australia. The energy and skill that have developed the company to its present prosperous condition assures success in the new fields.

In preparation for the expected larger trade extensive additions are being made by the Furukawa company to the treatment plants. At Nikko the capacity of the refinery is being doubled, and in Fig. 1, 2, and 3 is presented the flow-sheet and outline of the new mill for concentration of second-grade ore that was being built last fall at the mouth of the Tsudo adit at Ashio and which has since been completed. I am indebted to J. Kojima, engineer for the Tsudo mine, for these plans. The mill differs only in detail from those already in operation. The ores in the mine are separated into two grades known as first and second class. The first is raised by hand picking to a 12% copper content, and bagged for shipment to the smelter. The second, which averages 1% copper, is sent to dressing plants similar to the one illustrated in the accompanying figures. Essentially the ore is crushed, sized, jigged, and finally treated on tables. A peculiarity of the practice is the placing of picking tables at the head of the mill so as to sort out any remaining lumps of ore. The tables used are stationary, 8-sided, and horizontal. They are covered with boiler plate and have holes for delivery of waste and middling. The feed is through a vertical spout to the middle of each table, and around this spout is a rain of water which washes the ore as the picker rakes it toward the edge with a small cobbing hammer. Lumps of clean ore are thrown into a waiting car and the remaining material is directed to the appropriate outlet. The picking is done by women, who receive from 7½ to 12½c. per day, averaging about 10c. Women are also employed in spalling and picking out coarse rock where the ore is dumped over grizzlies and before it is wet, but none work underground.

Another interesting feature of the mill is the double cone illustrated in Fig. 4. These cones are placed ahead of the fine jigs. The pulp falls against a stream of rising water and three products are made; a lip-discharge which goes direct to the Callow cones and thence to tables, and two

spigot discharges which go to fine jigs. From the dimension drawing the construction of the cones may be readily seen. The size of the opening in the bottom of the inner cone is regulated by a hand-wheel and vertical screw as usual. The discharge of the inner cone is through an iron globe which fits like a valve in the bottom of the outer cone. To regulate the discharge of the latter, the inner cone is raised or lowered by a second hand-wheel.

Still a third peculiarity of practice in the Ashio mines is that of neutralizing, as well as settling, the waste water. This process, which has in view the protection from damage of crops grown in the valley below the works, has now been so perfected as to result in saving enough copper to pay for the extra work. Details of the process have been published in the *Transactions* of the American Institute of Mining Engineers (February 1912), by J. W. Richards, and need not be repeated. Briefly, the sand and slime are settled as perfectly as possible in a first pool, metallic hydrates are carried down in a second and third, in a fourth by means of 10 to 20% milk of lime, the neutralization and precipitation is advanced, and in a fifth it is completed. Finally in a sixth pool the water is run through a sand-filter before being sent back to the mill or allowed to escape. The water as it comes from the mills carries 0.00025% copper.

In the smelting and refining plants, as well as in the concentrating mills, there are many novel and interesting things to see. The ore is smelted in blast-furnaces with pot-roasting of the fine material and with the usual bessemer converters. Prior to the introduction of pot-roasting, which has become the common practice in copper smelting in Japan, the Furukawa engineers worked out a number of ingenious methods of handling the fine ore. Mr. Read has already mentioned the plan of making the ore into a ball and casting around it a thin shell of matte. On the whole, however, probably the most successful device is the briquetting machine invented by Sabro Watanabe, but four years out of school at Tokyo, and now an advanced student in Germany. Discarding the ordinary plunger and roll types of machines, he adapted the gravity stamp to the work. The moistened oil is fed to a horizontal revolving plate which carries it successively below six stamps each weighing 120 lb. and dropping 10 in. The plate moves 1½ revolutions per minute and stops eight times in each revolution; once to permit filling the hole in the plate which constitutes the mold, six times under successive stamps to receive one blow from each, and once for a plunger to clear the mold. The briquettes are 4 in. diameter, cylindrical, and 4 in. high. The machine requires but one man and 2 hp. It prepares 35 tons of briquettes in 24 hr., and the cost is 30c. per ton.

Another interesting little trick in practice is a plan for promoting smooth running of the blast-furnaces by feeding coal, when needed, through the tuyeres. This was devised, with the assistance of T. Watanabe, by Kosahu Asano, now head of the smelting department and a graduate of the Massachusetts Institute of Technology. The device has been described with drawings in *Metallurgical and Chemical Engineering*, by J. W. Richards. It consists in placing in each tuyere double flap valves that can be opened at will, and using a cylinder of 4 in. diameter and 12 in. long with a movable piston to force coal, first placed in the cylinder, through the tuyere and into the furnace. By this means a source of heat and reducing gases may be placed at will at any critical point. In practical operation fuel equal to about 3% by weight of the ore is thus introduced into the furnaces.

One of the most interesting features of smelting at Ashio is the neutralization of the furnace fumes. As the average amount of sulphur in the ore as it goes to the roasting plant amounts to 25%, and the smelter is in a narrow valley in the midst of a rich farming country while the climate is exceptionally moist, it is extremely important to prevent

drainage from escaping  $\text{SO}_2$  and  $\text{SO}_3$  in the fume. The plan in operation was devised by K. Asano, and while not entirely successful, is susceptible by careful work of greatly reducing the danger of damage. The smelting plant includes three blast-furnaces, each 160 by 42 in. at the tuyeres, and 11 roasting pots. The gases from both roasting and smelting plants, after passing through a dust-chamber, are conducted through a chimney sloping up the side of the mountain and broken at four places by vertical steps 40 ft. high. These are 12 by 12 ft. in cross-section, and at the top of each is an iron plate containing 200 1-cm. holes through which rains down a solution of lime water. This reacts on the  $\text{SO}_2$ , and to some extent on the  $\text{SO}_3$ , probably forming sulphites. It requires 40 cu. ft. of

water per minute and 300 lb. of burned lime per hour, to neutralize the gases, and they are reduced to a content of 0.5%  $\text{SO}_2$ . These purifying chambers are placed well up the hill so as to get the pull of the gases as far as possible. No fan is used, but one will probably need to be added when, as is planned, additional washing chambers are built. Last fall when the plant was visited the gas coming from the chimney was nearly colorless, only a slight yellowish tinge, perhaps from sulphide of arsenic, being seen. Further progress with this interesting process will be watched with interest, but enough has perhaps been said to illustrate the fact that Japanese mines are not only hives of industry, but also of invention, and are well worthy of careful study by mining engineers and metallurgists.

## Stacking Hydraulic Tailing

By W. W. EDWARDS

A novel method of handling the tailing from a hydraulic mining sluiceway has been devised by the North Columbia Gold Mining Co., under the management of J. M. Ruffner. This company operates hydraulic leases on Pine creek in the vicinity of Discovery, about six miles above Atlin, B. C. The method as shown in the illustration operates with poor dumping facilities, but with an abundance of water, and permits the handling of material cheaply by a new application of the monitor's stream. The company's ditch supplies 15,000 miners' inches to the giants under about 100-ft. head. This ditch, by the way, was dug by a steam-shovel mounted on a scow, which floated down an old ditch line, enlarging it from a previous capacity of 1000 miners' inches. There are two complete hydraulic installations about half a mile apart. The grade of bedrock on Pine creek here is only about one per cent. This makes impossible the disposal of tailing by ordinary means. A sluiceway 150 to 200 ft. long, with angle-steel riffles and block paving is ordinarily used, set on a grade of 3 or 3½ in. per 12-ft. box. The discharge end of the sluice is placed on clean bedrock. The grade used thus brings the sluice intake a foot or two above bedrock, but with the large amount of water available the material is easily driven into the sluice, through the action of four or five monitors used at the in-

take end. Ordinarily the dump would block this sluice immediately. Two or three monitors are placed at the lower end of the sluiceway with their streams directed at right angles to the tailing stream as it leaves the sluice. The heavier gravel, which would pile up in a heap, is thus forced to the side. Gradually a pile of tailing is started below the mouth and to the side of the sluice line. As this pile grows and the monitors continue to drive out more material, the stacking monitors are raised slowly, their streams following up the slope. When a monitor has driven its charge of gravel to the top of the pile, it is again lowered and the operation repeated. By this means the coarser gravel is all stacked. A good deal of the finer material is carried on down the creek by the water and fills up the creek bottom, but as this lower ground has been worked out already no harm results, especially as a great deal of this fine material is boomed out in the spring by the freshet and carried down to Atlin lake. The sluice-boxes are moved from one location to the next by teams and rollers. The piles of tailing look like dredge tailing and are about 15 to 20 ft. high, with slopes of about 2 horizontal to 1 vertical.

The abundant water-supply is also utilized to run an air-compressor which furnishes air for hammer-drills. These drills are used in breaking up the fallen slabs of clay overburden, thus saving blasting charges. High duty cannot be claimed for the water with the above described system of operation, but where, as in this case, water under a low head is plentiful, this method of tailing disposal has much to recommend it.

STACKING TAILING AT THE NORTH COLUMBIA MINES.

## Zinc Production of Utah

The production of zinc in Utah in 1911, according to Victor C. Heikes of the U. S. Geol. Survey, was 17,840,261 lb., valued at \$1,016,895, against 16,367,104 lb., valued at \$883,824, in 1910. This shows an increase of 1,473,157 lb., or 9%. The Park City mining district alone produced 8,596,564 lb. of zinc in 1911, and the Bingham district 4,715,121 lb. The zinc concentrate, amounting to 13,156,682 lb., all came from Salt Lake, Summit, and Wasatch counties. There were 208 mines producing gold, silver, copper, lead, or zinc in 1911, against 183 in 1910. The total quantity of ore sold or treated in Utah in 1911 was 7,268,530 short tons, an increase of 879,132 tons. The average total recoverable value per ton was \$5.07 in 1911,

against \$5.04 in 1910. The average value per ton is low on account of the large tonnage of copper ores, of which 6,121,099 tons was sold or treated. Of the total ore of all classes, 267,111 tons went to gold and silver mills, 5,840,091 tons to concentrating mills, and 1,103,054 tons to smelters.

The production of lead in Nevada in 1911 was 3,263,657 lb., valued at \$146,865, against 4,871,130 lb., valued at \$214,329, in 1910, a decrease of about 33%. Lead decreased in all counties but Clark and Douglas. The mines of Clark county, the largest producer, yielded 1,629,571 lb., an increase of 319,887 lb. over the production of 1910.

The Premier Diamond company employed 11,865 natives during 1911.

# Impressions of the Comstock

By THOMAS T. READ

The modern American resembles the ancient Athenian in that new things engage the greater part of his attention. Though the Comstock orebodies are in many ways the most remarkable in the world—the hottest, and richest, at one time the most studied, and now the most neglected, the scene of the invention or devising of many useful appliances and methods of work, developed by the deepest shafts and equipped with the finest machinery of their time—they have now sunk to the status of counters in the game of stock-selling. Their rôle in the history of mining in America has been one with which every engineer should be reasonably familiar, but engineers of the younger generation, while no stranger to the South African ‘banket’, the ‘reefs’ of Australia, and the placers and mines of South American countries, commonly retain only vague memories of a hasty perusal of the volumes by ‘Dan de Quille’, of Church, Lord, Riehthofen, King, and others; books so eagerly read thirty years ago, but now quietly gathering dust upon the shelves undisturbed, except for the moment by some curious student. Twenty-five miles north of the lode, hundreds of engineers pass and repass yearly along the main line of the Southern Pacific railroad, but almost none linger by the way to follow the course of the Virginia & Truckee railroad as it winds up from Reno in the valley of the Carson river to Virginia City, a distance of sixty tortuous miles, though the direct road is but 25 miles long.

The traveler, however, who makes the journey begins to be repaid from the first moment of leaving the main line. The yellow cars of the Virginia & Truckee, waiting at the main-line station, look as though they might be well preserved specimens of the first rolling stock of the road. The story is told that in 1868 William Sharon, then local agent of the Bank of California but fast budding into a captain of finance, sent for Isaac E. James, the leading surveyor of the district, and asked him whether he could run a road from Virginia City to the Carson river. “Yes,” was the reply. “Do it, then, at once,” was the rejoinder, and before the end of 1869 trains were running from Carson to Virginia City over a track  $13\frac{1}{2}$  miles long, with a total curvature of seventeen full circles, with a maximum grade of 116 ft. to the mile, Virginia City being at 6200 ft. elevation and Carson City 1575 ft. lower. It is recorded that the line was built by Chinese labor, and confirmatory evidence is found in the interior of the cars, which surely were decorated by Chinese artists. As the train pulls out through the valley of Steamboat creek and across a low divide into the Carson valley, one accustomed to the gray deserts which border the main line is astonished at the verdure of these surprisingly green and broad valleys.

Carson City is quickly reached, but yields a sense of disappointment, for it seems more like a New England county seat than the capital city of what is, in many ways, the most remarkable mineral-producing state of the Union. Still, it is scarcely fair to judge any city by that portion of it visible from the railroad, unless, like Cincinnati, it is so conveniently inclined as to present the whole expanse to the observer in a car window. After leaving Carson City, the train soon begins to follow the course of Carson river, and the ruins of the early mills are conspicuous objects. Henry De Groot has described\* vividly and in detail the pioneer mills, and their builders, and I will only note here that the first mill in Nevada was built in 1860 by Almarin B. Paul, four miles south of Virginia City, near Gold canyon, and his first contracts provided for a treatment charge of \$25 to \$30 per ton, even though the ore crushed was richer in gold than in silver. Some of the later mills were remarkable. The Ophir mill, near Lake Washoe, covered an acre of ground, and it is re-

corded that up to April 1, 1862, some 3000 tons had been milled at a cost for milling, freight, and office expense of \$115 per ton. The Gould & Curry mill was built in the form of a Greek cross at a cost of \$900,000. After treating about 5000 tons of ore, at a cost of nearly \$50 per ton, it was remodeled, almost from the foundations, at a cost of \$560,000. It need not be added that the first two decades of the history of the Comstock was a period of romance and prodigality. Fortunes were quickly made, and often as quickly dissipated. Only men of balance and a sense of proportion retained their gains and made them a basis of solid prosperity. Fair, Mackey, Flood, O'Brien, Sharon, Jones, and others thus became prominent figures in the world of finance, while scores with less balanced judgment threw their winnings into hare-brained schemes and saw them vanish as quickly as they had come.

By the middle of 1880 the Comstock had produced \$306,000,000, not including the tailing, which averaged over \$43 per ton, or nearly \$50,000,000 more. Over one-third of this, or \$108,861,230, was produced by a single bonanza found in the Consolidated Virginia, California, and Ophir, from a little over a million tons of ore. The early records are contradictory, but it has been estimated that 16 bonanzas produced \$272,000,000 from 6,350,000 tons of ore; an average yield of nearly \$43. In 1879 the issued capital of the companies which had been formed was \$364,000,000, and only \$116,000,000 in dividends had been paid.

Only about a third of the gross output of the mines had trickled through to the shareholders in dividends. But it must not be rashly assumed that all the remainder was wasted. The machinery of present-day mining and milling was then in process of development, and the development of machinery and processes on high-grade ore is ever fatal to the dividend account. Pumping was expensive, too, for the Sutro tunnel did not hole through into the Savage mine until July 1878, and it was almost a year later before it became effective for drainage, while the Ophir, for example, had been pumping 146,000 gal. per day in 1872, using wood-burning engines, operating at a cost of \$72,000 per year. The cost of the Sutro tunnel is interesting. The main part is 20,489 ft. long and cost \$2,100,000, and, since the contracts between the mining companies and the tunnel company provided for a royalty upon the ore hoisted instead of a charge for the amount of water pumped into the tunnel, it was indeed hard lines that it reached the lode only at the end of the period of bonanza ore production and has since served to drain mines that continue to exist largely upon assessments. In a way the Sutro tunnel was a tremendous disappointment. The Government commission appointed in 1871 reported that it would be of great practical value in exploring the ground east of the lode, but its service for drainage and ventilation would not be commensurate with its cost. The investors expected large returns from the royalty of \$2 per ton of ore hoisted from the mines which it drained. But it proved valueless in prospecting (as most deep-level adits do). It has carried away rivers of water from the mines in the past thirty years, but the greater part of all the output of the Comstock had already been hoisted before the tunnel was completed.
